To the solid ground
Of Nature trusts the mind which builds for aye —WORDSWORTH

THURSDAY, NOVEMBER 1, 1906

SOME RECENT WORKS ON LOGIC

(1) *Symbolic Logic and its Applications.* By Hugh MacColl. Pp. xi+141. (London: Longmans, Green and Co., 1906.) Price 4s. 6d. net.

(2) *The Development of Symbolic Logic.* By A. T. Shearman. Pp. xi+242. (London: Williams and Norgate, 1906.) Price 5s. net.

(3) *An Introduction to Logic.* By H. W. B. Joseph. Pp. vii+564. (Oxford: Clarendon Press, 1906.) Price 9s. 6d. net.

(4) *Thought and Things, or Genetic Logic.* By James Mark Baldwin. Vol. i. Functional Logic, or Genetic Theory of Knowledge. Pp. xiv+273. (London: Swan Sonnenschein and Co., Ltd., 1906.) Price 10s. 6d. net.

(1) WHETHER Mr. MacColl is the Athanasius of symbolic logic or only its Ishmael, the fact remains that he seems unable to come to an agreement with other exponents of the subject. But he contends that his system "in the elastic adaptability of its notation bears very much the same relation to other systems (including the ordinary formal logic of our text-books) as algebra bears to arithmetic." The present work contains the results of a series of researches dating from the year 1872. Portions have appeared at intervals in various magazines, English and French. Points on which he lays considerable stress, and in which he does not command the uniform assent of the other symbolic logicians, are these:—(a) that he takes statements and not terms to be in all cases and necessarily the ultimate constituents of symbolic reasoning; (b) that he goes quite beyond the ordinary notation of the symbolists in classifying propositions according to such attributes as true, false, certain, impossible, variable; (c) that in regard to the existential import of propositions, while other symbolists define the null class 0 as containing no members and understand it as contained in every class, real or unreal, he, on the other hand, defines it as consisting of the null or unreal members 0_1, 0_2, 0_3, &c., and considers it to be excluded from every real class. A chapter is devoted to the solution of Prof. Jevons's so-called inverse problem.

(2) The sub-title of Mr. Shearman's work is "A Critical Historical Study of the Logical Calculus," and its author's chief object is to show that during the last fifty years a definite advance has been made by symbolic logic.

"I have traced the growth of the subject," he writes, "from the time when Boole originated his generalisations to the time when Mr. Russell, pursuing for the most part the lines laid down by Peano, showed how to deal with a vastly wider range of problems than Boole ever considered."

He is careful to point out that the view which he expresses in his work as to the relation of mathematics to logic "is to be regarded as preferable only to the doctrines that were in vogue prior to the time of Peano's analysis of mathematical notions."

Mr. Shearman's opinions on some disputed points may be noted:—(a) He can see no valid reason why symbols may not designate now classes and now propositions. The only thing to be remembered is that the rules of procedure are not quite the same in the two cases. (b) He rejects all attempts to deal with any but assertoric propositions, and holds that if Mr. MacColl wishes to work with such data as probable and variable he should introduce new terms. (c) He regards it as practically impossible to elaborate a calculus based on intension.

In a footnote he directs attention to a remark of the late Prof. Adamson which seems to imply that all the intermediate processes in a solution ought to be intelligible. Our author believes, on the other hand, that "a calculus is a means of reaching correct conclusions by means of the mechanical application of a few logical rules, and it is quite possible that in the application of such rules unintelligible elements may temporarily appear." The doctrines of Prof. Jevons and Mr. MacColl are subjected to some severe criticisms, and Mr. Shearman holds that Prof. Jevons's actual contributions to the development of symbolic logic were few and relatively unimportant.

The last chapter contains a warm defence of the utility of symbolic logic, though the author does not claim that it can be used directly by natural science

(3) Mr Joseph's work is on very different lines from the two foregoing It is an excellent and very sound exposition of the traditional logic for which Oxford has been famous ever since the days of Chaucer's Clerk But if the matter is traditional, the manner of exposition is as fresh and independent as it could well be, and the author has entirely fulfilled the desire expressed in his preface not to teach anything to beginners which they should afterwards have merely to unlearn Especially valuable are some of the discussions of particular topics, *e g* of the *principium individuationis* (on p 76), or (on p 275) of the passage from Aristotle's "Categories" which is sometimes quoted as a source of the "Dictum De Omni" We note, too, Mr Joseph's irresistible objections to classificatory division by dichotomy, so zealously defended by Jevons and the others who won our earliest logical sympathies, and his rejection (in excellent company) of the doctrine of the inverse relation of extension and intension

Mr Joseph has interesting remarks to make on the relation between mathematics and logic, and a good statement of the doctrine that the principle of syllogistic inference cannot be made into the premiss of a particular syllogism without begging the question His chapter entitled "The Presuppositions of Inductive Reasoning the Law of Causation," is a model of clear and forcible reasoning Mill's four methods, he finds, may be reduced to one "method of experimental inquiry," which is ultimately based on disjunctive reasoning, and the essence of which is "that you establish a particular hypothesis about the cause of a phenomenon, by showing that, consistently with the nature of the relation of cause and effect, the facts do not permit you to regard it as the effect of anything else"

There is a valuable seven-page discussion (pp 352–8) of the inductive syllogism in Aristotle, whom the author seeks to defend—not without qualifications—from the objection that, after all, his induction rests on complete enumeration, and that thus *deduction* from any premiss so gained becomes a hollow pretence Where the units are species, he points out, and one wants to prove something about the genus to which they belong, complete enumeration is possible and legitimate but where the units are individuals, one does not (according to Aristotle) work by an inductive syllogism that summons all the instances, one learns the essential nature of the species to which they belong by induction, but the induction is now a psychological rather than a logical process, and we arrive at the conclusion, not through an inductive syllogism, but "in virtue of the necessary relation between the two terms which our familiarity with particulars makes possible, but which is the work of intellect or *nous*" We should have welcomed in this connection a detailed exposition of some of the difficulties in the concluding chapter of the Posterior Analytics

(4) This volume is the first instalment of what promises to be an important inquiry, "inductive, psychological, genetic," into the actual movement of the function of knowledge The author distinguishes genetic logic from formal (or the logician's) logic, and metaphysical logic (or logicism), and he describes genetic logic as the physiology and comparative morphology of knowledge—physiology because it examines function, and comparative morphology because "it asks about the relation of the forms and other logical determinations of the several modes of cognitive process to one another, and aims to make out an interpretation of the series of forms as conditioned upon functions"

Prof Baldwin's account of the process by which cognition is built up is so coherent and intricate that it is impossible to give more than a fraction of its substance here He begins with the condition of bare awareness of an object, the a-dualistic consciousness, examines the place of interest as a factor in the determination of the object, and the meaning of various terms like *disposition, autonomic, heteronomic, control, project, reality coefficient*, shows how "it is the stimulation, not the response, that is the controlling factor in the construction of sense objects," and how the first distinction is made in the perception of persons and things Then he passes to image objects and memory objects, and discusses the process by which the inner-outer dualism is reached This leads him to an examination of play or make-believe objects, and then we have three valuable chapters on various aspects of meaning The last two chapters deal with the mind-body dualism and the dualism of subject and object

The terminology of the work is not of the simplest but behind it one finds that the writer has something true and important to say Two other volumes—one on experimental logic and one on real logic—will complete the work, which is being published simultaneously in English and French

A MANUAL OF PHARMACOLOGY

A Manual of Pharmacology By Dr. W E Dixon Pp xii+451, numerous curves, diagrams, and formulæ in the text (London Edward Arnold, 1906) Price 15*s* net

PHARMACOLOGICAL literature in the English language has during the last few years increased considerably, and this is true even if we exclude the copious additions to this literature emanating from America Students of pharmacology at the present time have at least three exhaustive text-books to choose from, all up to date, and written by teachers actively engaged both in teaching and original research In each of these works the classification of the subject adopted is markedly different, from which, perhaps, the philosophical reader would be apt to infer that in the present state of our knowledge, whether of the action of drugs or of the chemical composition of their active ingredients, no absolute classification is possible In the book before us prominence is certainly given in determining classification to the physiological action of the drugs in question, and in the present

state of our knowledge perhaps a classification based upon such principles is the most satisfactory The matter is, however, one of considerable difficulty, as nearly all drugs exert many physiological actions not always differing only in degree, but in some cases actually in kind It is, from the nature of the case, therefore obligatory to take one action of a drug as determining its position in one or other group As an instance we may cite caffeine Dr Dixon places this drug by virtue of its action in the group of diuretics, if we, however, follow the text we find that considerable space is of necessity devoted to the other, almost equally important, actions of this alkaloid

It is difficult in a review of ordinary dimensions to do adequate justice to a work of this character, and in the remarks which follow we shall confine ourselves to a few salient points which strike us as being likely to interest the medical and general scientific reader In the first place, it seems that on account of the entire absence of all reference to original literature the book is not intended to be a book of reference, further, the absence of information with regard to pharmacological technique obviously places the book in the library rather than in the laboratory As the author states clearly in his preface, several of the facts are new, and doubtful statements have been verified by experiments performed in his own laboratory In this connection we must say at once that the reader will have carefully to consider the magnitude of the evidence with regard to these new facts and verifications of doubtful ones The therapeutics included in Dr Dixon's work are only such as to illustrate the pharmacology, from this it clearly follows that the book is not intended for those engaged in the practice of medicine Materia medica is only briefly dealt with, although in many cases very abstruse details and complicated formulæ with regard to the chemical composition of substances, such, for instance, as hydrastine, are given We think such details cannot be of use to the ordinary student of pharmacology, and to be of any value to the pharmacological or chemical worker should be accompanied by a reference to the literature from which they are derived, and here we will observe that although in his preface the author mentions a list of standard works dealing with pharmacology and materia medica to which he is indebted, all reference, so far as we can find, to books dealing with the question of the chemical composition and reactions of, for instance, the alkaloids and their derivatives is omitted

The first thirty-eight pages of the book are devoted to general considerations, amongst which perhaps the most attractive is a discussion of the relation between physiological action and chemical constitution This interesting subject is treated at some length, and most of the important facts bearing upon it are carefully considered Under the heading of the standardisation of drugs, the author discusses the question of physiological standardisation He rightly directs attention to the extreme difficulty of standardising certain preparations according to their chemical content, and we entirely agree that, in the case of certain drugs, standardisation of a physiological type should be adopted, that is, different preparations should be compared with regard to their action upon a constant tissue unit Such a method has been successfully adopted, under even more complicated conditions, in the comparison of the relative toxicity of certain sera We must confess, however, that we are in this connection somewhat surprised to read that the cardiac glucosides can be standardised by perfusing the isolated rabbit's heart with Ringer's solution and subsequently adding the drug The author must either be under some misconception with regard to the composition of Ringer's solution or be in possession of important facts which, so far as we are aware, he has not published

From chapter iii on, the book is devoted to descriptions of the characters, preparations, and physiological actions of the official, and some important unofficial, remedies and drugs The action of each drug is most exhaustively considered, and in most cases illustrated by one or more curves, the result in the vast majority of cases of the author's own experimentation The amount of space devoted to these curves is certainly a feature of the work, and renders to it, at least from one point of view, a unique value, as, however, usually no discussion of the conditions of the experiment accompanies the curves, the reader has too often to take upon trust the conclusions based upon them

The mass of the pharmacology of the more purely inorganic substances is prefaced by a short but complete discussion of salt action and some of the chief bearings of modern physical chemistry upon pharmacological action

The final chapter of the book is devoted to ferments vegetable toxins, internal secretions, serum-therapy, and antagonism The work concludes with an exhaustive index

Dr Dixon's "Manual" is certainly an important addition to standard pharmacological literature, and if in our opinion its educational value, taken as a whole, is less than that of certain of its contemporaries, this is to some extent due to the curious position its subject matter holds in the complicated medical education of to-day We have no hesitation in saying that it should be possessed by every pharmacologist and pharmacological laboratory, if only as containing a number of original experimental results worthy of control and further investigation

A PIONEER IN BIOLOGY

Jan Ingen-Housz Sein Leben und sein Wirken als Naturforscher und Arzt By Prof Julius Wiesner Unter Mitwirkung von Prof Dr Th Escherich, Prof E Mach, Prof R von Toply, und Prof Wegscheider Pp x+252 (Vienna C Konegen, 1905)

DR WIESNER relates that on his becoming professor of plant physiology in the University of Vienna, more than thirty years ago he resolved to become familiar with the work of the founders of that science Soon he became peculiarly interested in

the labours of Ingen-Housz, and found that his real worth had not been recognised Much information was gathered that showed how many-sided his activities had been in science and in medicine, and Prof Wiesner was induced by the meeting of the International Botanical Congress at Vienna to present the results of his labour of love in this volume It must rank as a classic, admirable as a biography of a leader in research and as a history of scientific progress in a most important field of study

Jan Ingen-Housz was born at Breda, in Brabant, South Holland, on December 8, 1730, and attended the higher school there until the age of sixteen, after which he continued his education in the Universities of Louvain, Leyden, Paris, and Edinburgh, even after he had graduated (at the age of twenty-two) in Louvain From 1757 to 1765 he practised medicine in Breda, but after the death of his father, he went to London, on the invitation of Sir John Pringle, the King's physician Here he became acquainted with distinguished anatomists and medical men, and made a study of the method of inoculation for small pox From London he went to Vienna, by the wish of the Empress Maria Theresa and introduced the use of inoculation there

He frequently visited Switzerland, France Holland, and England For the last country he had an especial affection, regarding it as the land in which science was most honoured and furthered He died in 1799, near London, while on a visit to the Marquis of Lansdowne

Ingen-Housz approached the research which has brought him most fame -the relation of plants to the atmosphere—from the standpoints of the physicist and chemist rather than the botanist, and with a view to the value of green plants exposed to daylight as purifiers of the atmosphere from the products of animal respiration He had busied himself with the physical problems of electricity, magnetism, optics, and heat and had made useful contributions to their investigation His researches in chemistry led to improvements in the preparation of matches and in other matters of practical value

A very valuable advance in microscopical technique introduced by him was the use of a cover over the drops of water or other fluids in which the objects were included for examination At first the covers were made of mica, but soon he employed thin glass covers, as is now the custom

His researches into the nutrition of plants were for the most part carried on during his stay in Vienna, although his first work on the subject was published in London in 1779 under the title "Experiments upon Vegetables, discovering their great Power of Purifying the Common Air in the Sunshine and of Injuring in the Shade and at Night" It was soon issued in German and Dutch translations

When Ingen-Housz began the researches that led him to such great results it was generally taught that plants extracted from the soil the materials of which they were in want in the conditions in which they exist in the plant, and that nothing of importance required to, or did, pass off from plants That gas was given off had been determined by Priestley and by Scheele, who had investigated the relations of green plants with the atmosphere, but Priestley arrived at the conclusion that these plants always freed the atmosphere from the "fixed air" (carbon dioxide) emitted by animals and emitted "dephlogisticated air" (oxygen), and Scheele believed that they always added to the amount of the "fixed air"

Ingen-Housz succeeded in showing that both these eminent chemists were right in part, the green parts in daylight emitting "dephlogisticated air," while parts not green at all times, and even green parts in darkness, like animals, emitted "fixed air" His views were combated, even Priestley joining in attacking them, and by his authority preventing their importance from being recognised as it deserved to be.

The new foundation for chemical investigation afforded by Lavoisier's discoveries was made use of by Ingen-Housz to explain more fully the nutrition of green plants than had been possible until the recognition of the composition of the "dephlogisticated air" and the "fixed air," and he showed that the carbon contained in plants is derived from the carbon dioxide of the atmosphere instead of from the soil as had been supposed by Senebier He also showed that the carbon could be acquired by green plants only in light, and that carbon dioxide beyond a limited degree of concentration in the atmosphere proved harmful even to plants as well as to animals He thus distinguished between the respiration and the assimilation in plants, a distinction not fully realised or taught by botanists until many years later The value of humus and of vegetable manure as food for plants he ascribed, not to the substance being directly employed by the plants as food, but to its effect on the mineral contents of the soil, which were rendered more easy of absorption, and he demonstrated that diluted mineral acids produced similar beneficial effects His later views on the nutrition of plants are given in "An Essay on the Food of Plants and the Renovation of Soils," which is contained in a collection of essays (in which it is No 3) issued under the title "Additional Appendix to the Outlines of the Fifteenth Chapter of the Proposed General Report from the Board of Agriculture on the Subjects of Manures," London, 1796

An appendix stating the sources of information about Ingen-Housz, with extracts from letters and a bibliography of his writings, adds to the value of the volume and supports Prof Wiesner's claim that he must be classed among the founders of botany, and that he showed singular ability also as an investigator in physics and in medicine

ANALYSIS OF PAINTS

The Chemistry of Paints and Paint Vehicles By Clare H Hall Pp vi+134 (London Constable and Co, Ltd, 1906) Price 8s net

THIS book or booklet is not intended to appeal to the artist the house painter or the manufacturer, but to the young analyst who has had little or no experimental acquaintance with the materials discussed in its pages The scope of the volume is indeed extremely limited, since it deals with the ex-

combination of only a few common pigments, and by no means exhaustively even with these, about some vehicles and diluents the information to be found in these pages is less meagre.

There are five chapters in this book, an appendix containing thirteen tables, and an adequate index. Chapter i. is devoted to the determination of certain constituents of common paints, and deals with aluminium, barium, carbon dioxide, chromium, iron, lead, magnesium, manganese, silicon, sulphur, and zinc. In this chapter, which occupies only fourteen pages, we are struck with the inadequate, and even puerile, drawing of the CO_2 apparatus shown in the figure on p. 3, and with the confused nomenclature of the two oxides of chromium. For example, on pp. 4 and 5 we are told that "all chromate compounds must be changed into the chromic state, which is indicated by an intense green color," and that this "green color is due to chromic salts." The omission of any caution as to the non-volatile impurities commonly occurring in the hydrofluoric solution used in ascertaining the purity of silica is unfortunate.

The properties of a few common pigments, such as Prussian blue, ultramarine, ivory-black, umber, Vandyke brown, the mixture of lead chromate and Prussian blue wrongly called chrome green, iron-red, genuine and imitative vermilion, a number of white pigments or adulterants, chrome yellow, red lead, yellow ochre, and the siennas are dealt with. This list serves to show how many of the finer and choicer pigments, namely, aureolin, cadmium yellow, viridian, and cobalt-blue, are excluded from consideration. Nor can we agree with everything we find in these pages. Ivory- and bone-black are not "*combinations* of carbon, hydrocarbons, water and mineral matter." Graphite does not possess a "*brownish* gray" colour, and there are many words wrongly spelt in this chapter, such as analine for aniline, and limonite for limonite.

The examination of actual paints, and of such as are mixed ready for use, is dealt with in the third chapter. The preliminary treatment of oil paints necessary before they can be tested or analysed is duly described. Chapter iv. is concerned with the matching of samples, while the final chapter is devoted to vehicles. Here will be found a more adequate, detailed treatment of the subject. On pp. 89–92, for instance, the curious drying oil called Chinese wood oil is described. This oil is used largely both in China and Japan, and is imported into America and Europe in increasing quantities. It is obtained from the seeds of *Aleurites Fordii* (Hemsley) and of other species of the same genus, as *A. cordata* and *A. trisperma*. Mr. C. H. Hall states (*loc. cit.*) that this oil, if heated to 285° C. to 300° C., suddenly solidifies into a jelly which is no longer soluble in the usual solvents, and cannot be reduced again to the liquid state. Mr. Hall's statement that Chinese wood oil, even in small proportion, confers upon paints the property of drying without gloss, and may be used as a substitute for wax in painting media intended to produce a dull or matt surface, seems to merit particular attention.

The thirteen tables of constants, coefficients, and specific gravities which constitute the appendix to this volume will be found useful by the analyst. There is a full index.

This little book, with all its imperfections and its immaturity, is not destitute of merit.

OUR BOOK SHELF

British Rainfall, 1905. (Forty-fifth annual volume.) By Dr. Hugh Robert Mill. Pp. 271. (London: Edward Stanford, 1906.) Price 10s.

THE forty-fifth issue of this annual volume tells us better than any mere description could do of the healthy and active state of this voluntary rainfall organisation. When it is considered that more than 4000 individuals scattered over the British Isles read their rain-gauges at 9 o'clock every morning, enter their results on a form, and send in monthly returns to the central bureau at 62 Camden Square, and do all this voluntarily, it is impossible not to admire this band of enthusiasts for their united efforts in so good a cause.

The valuable collection of rainfall statistics is not, however, allowed to lie idle, for the energetic head of this organisation, Dr. H. R. Mill, with his small staff, brings all the facts together and discusses the distribution of this rainfall both in space and time.

The present volume shows how well this work is carried out, and the observers must feel a great amount of satisfaction in seeing their united efforts so ably handled. Fronting p. 64 is a map indicating the positions of the 4006 rain-gauges at present in use, and one can see at a glance the districts where observers are urgently needed. Ireland and north and central Scotland are conspicuously in need of more volunteers, and it is hoped that many of the places mentioned in the text will soon be counted among the recording stations.

As meteorological readers of NATURE are fully acquainted with the general arrangement of the matter in these annual volumes, it is only necessary in this notice to direct attention to some of the discussions on the collected statistics. Thus, after a brief review of the recent important publication on the "Precipitation in the North German River Basins," compiled by Prof. Hellmann, we are presented with some valuable data on the relation of evaporation from a water surface to other meteorological phenomena. The section on heavy falls on rainfall days in 1905 will be found very interesting reading, and the numerous maps show at a glance the distribution of these falls over the country. After sections dealing with the distribution of rainfall in time and a discussion of monthly rainfall, we come to the relation of the total fall of rain in 1905 to the average. To sum up in a few words the result of this discussion, it may be said that for the whole of England and Wales the general rainfall for 1905 was 16 per cent. below the average. In fact, so low was this figure that "except for 1902 and 1893 there has not been so dry a year in England since the memorable drought of 1887." It will be interesting to see how the present year's rainfall statistics compare with those of 1905. In 1905 Scotland as a whole had a deficiency of 5 per cent., while Ireland suffered to the extent of 12 per cent.

In addition to a great number of tables, the text is well supplied with numerous suitable maps and illustrations, making the volume a valuable summary of British rainfall for the past year.

W. J. S. L.

Technical Thermometry Pp ix+62 (Cambridge The Cambridge Scientific Instrument Co Ltd 1906)

This pamphlet contains detailed illustrated descriptions of the various types of instruments for temperature measurement made or sold by the Cambridge Scientific Instrument Co which has long been in the front rank in the manufacture of electric thermometers of all kinds

It deals first with the well known platinum resistance thermometers of the Callendar Griffiths type These are made in many different forms Among the most interesting of the apparatus used in connection with them is the ingenious direct reading temperature indicator which gives without any calculation the direct centigrade or Fahrenheit temperature on the air scale with a sensitiveness of considerably less than 1° up to 1 00° C The various types of resistance boxes used in accurate platinum thermometry are all arranged to be capable of self verification We believe that this self testing type of resistance box was among the first examples of a high-class physical instrument intentionally arranged by the makers to encourage periodical standardisation by the user rather than complete dependence upon the original adjustment The Callendar recorders in their various forms can now be made to give with very low energy consumption continuous records of resistance temperature radiation E M F current or power within very wide limits

Among the thermoelectric appliances is a new form of recording millivoltmeter in which the galvanometer boom is depressed every half minute on to an inked thread thereby leaving a dotted record on the paper The instrument can be made sufficiently sensitive for recalescence curves The radiation pyrometers of Prof Féry are also described and illustrated In these the radiation from the object the temperature of which is to be measured is concentrated upon a minute thermocouple at the focus of a mirror or lens and the E M F set up is measured in the ordinary way by a suitable millivoltmeter

In an appendix are given an excellent summary of the principles of electric thermometry with tables of constants and a list of trustworthy melting and boiling points obtained from the National Physical Laboratory also a good bibliography of recent thermal research

Astronomischer Jahresbericht Band vii Literature of 1905 By A Berberich Pp xxxviii+646 (Berlin Georg Reimer 1906) Price 20 marks

This volume is the seventh issue of a series of most useful compilations and it is a matter of deep regret that the founder and chief worker of such an admirable publication is no longer with us Herr Walter Friedrich Wislicenus died last year on October 3 but as we are told by Dr Walter de Gruyter in a brief obituary notice he contributed a considerable portion of the present volume The frontispiece to this issue therefore fittingly presents us with an excellent portrait of the founder whose place is now taken by Herr A Berberich

With regard to the book itself little need be said except that the high standard of former years has been maintained The 600 pages of references with their brief and concise abstracts cover the domain of astronomical literature for the past year and a very complete name index concludes the volume It may be incidentally remarked that the total solar eclipse of August 1905 is responsible for no less than ninety five references, which help somewhat to increase the bulk of the present volume

Zoologischer Jahresbericht für 1905 Herausgegeben von der Zoologischen Station zu Neapel Redigirt von Prof Paul Mayer (Berlin R Friedländer und Sohn 1906) Price 24 marks

The always welcome Naples Jahresbericht" appears as usual well up to time and its familiar features remain unchanged Purely taxonomic papers are not included in the programme but this limitation has been generously interpreted by some of the recorders Where we have been able to test the lists we have found them full and accurate and many of the summaries are models of terseness and clearness If we look at the first section we are at once struck with the rapidly increasing number of important researches on the Protozoa if we look at the last section we are similarly impressed with the number of papers dealing with Mendelian phenomena The indefatigable editor Dr Paul Mayer is responsible for the reports on Protozoa Bryozoa Brachiopoda on part of the Arthropoda and on general biology—truly a heavy piece of work for a man who does so much else To him and to his *collaborateurs* we offer in the name of zoologists our hearty thanks

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return or to correspond with the writers of rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Absorption of the Radio active Emanations by Charcoal

PROF RUTHERFORD in his interesting letter in NATURE of October 25 (vol lxxiv p 634) on the Absorption of the Radio-active Emanations by Charcoal has no doubt quite unintentionally mistaken the general results of my experiments and therefore I feel that some slight addition ought to be made to his communication

In the first paragraph of his letter Prof Rutherford says that the interesting property of certain kinds of charcoal notably that of the cocoa nut of rapidly absorbing gases *except the inert gases belonging to the argon family* is now well known since the recent experiments of Sir James Dewar

Now the statement made in the part of the paragraph I have italicised is not accurate In my papers entitled The Absorption and Thermal Evolution of Gases Occluded in Charcoal (Proc Roy Soc 1904) The Separation of the more Volatile Gases from Air without Liquefaction (Proc Roy Soc 1904) Nouvelles Recherches sur la Liquefaction de l Helium (*Comptes rendus* 1904) and New Low Temperature Phenomena' (Proc Roy Inst 1905) I have shown that all the inert gases without exception can be condensed in charcoal as effectively as ordinary gases provided corresponding conditions of temperature pressure and concentration are maintained

In speaking of the many avenues for future inquiry opened up by the charcoal method of separating gases I said (Proc Roy Soc p 130 1904) — The method I have described will be equally applicable to the treatment of the gaseous products from minerals containing helium hydrogen &c and also to the radium products of the same kind It seems even probable that the separation of the less volatile constituents in the air may be improved by a slight modification in the mode of working As a matter of fact at the time of these communications to the Royal Society in 1904 I had made a few experiments on the condensation of the radium emanation by charcoal *in vacuo* and also on the separation of krypton and xenon but during the last two years my health has been so indifferent that many lines of investigation have had to be abandoned In my Royal Institution lecture of June 6 1905 I ex-

plained and exhibited the process of separating krypton and xenon, showing that a proportion of less than a millionth of these constituents in the atmosphere can be condensed and concentrated in charcoal cooled to the temperature of liquid air Turning again to Prof Rutherford's letter, his surprise about the absorption of the emanation of radium thorium, and actinium by charcoal on the ground of being inert gases may be dismissed as nothing more than what we should anticipate but the temperature at which the absorption by charcoal takes place raises some important questions

To take an illustration (Proc Roy Inst 1905) I have shown that charcoal cooled in solid carbonic acid at the temperature of 195° ab is capable for a time of absorbing the carbonic acid present in air (amounting to, say 3/1000 of an atmosphere) until the concentration rises to about 1 per cent of the weight of the charcoal If on the other hand the separation of the carbonic acid from the air had to be done by cooling alone then the temperature of the air must be reduced below 129° ab and about 100° ab it would for practical purposes be nearly all removed Thus charcoal about twice the absolute temperature required for condensation by mere cooling is for a small concentration of the gas undergoing absorption equally effective We can compare now the behaviour of the radium emanation with that of carbonic acid In the paper of Rutherford and Soddy on the condensation of radio active emanation (*Phil Mag* 1903) it is shown that the temperature has to be lowered below 138° ab in order to condense the radium emanation while it is complete by 123° ab By analogy therefore we anticipate that at twice 138° ab charcoal would still act as a condensating agent This then brings us up to about the ordinary temperature just what Rutherford has found to be sufficient Such comparisons however may not necessarily mean that the radium emanation is comparable in volatility with carbonic acid at low temperatures

The results of Rutherford and Soddy would seem to show that the radium emanation has a high latent heat of volatility and consequently by all analogy a high boiling point Thus they say (*Phil Mag* 1903) that the radium emanation begins to volatilise at 118° ab and by 119°5 ab the amount is increased four times If we accept the view that the partial pressures of the emanation were in the ratio of one to four at the two temperatures given above then we may apply the Rankin formula ($\log P = A - B/T$ where A and B are constants P the pressure and T the absolute temperature) and find the order of the value of the B which is proportional to the molecular latent heat which in this case comes out 5662 Taking again the relative electrometer leaks by the statical method of 5 3 at 126°5 ab and 0 74 at 124°5 ab this gives 6735 which is of the same order of magnitude The following values of the B constant for different bodies are useful for comparison —

	B constant
Sulphur (solid)	4599
Mercury (liquid)	3170
Phosphorus (liquid)	2570
Carbonic acid (solid)	1353
Argon (liquid)	339
Xenon (liquid)	669

The calculated value of the B constant of the radium emanation is then twice the value for mercury and nine times the value for xenon We need not press however the accuracy of the latent heat constant of the radium emanation too far so let us divide it by two which will make it of the order of the latent heat of mercury or phosphorus Accepting for the moment such a value of the molecular latent heat we cannot avoid inferring that the boiling point of the emanation may be relatively higher than one at first might anticipate Even if we assume that the emanation represents a gas two steps higher in the periodic series than xenon the B constant would by analogy be only a little more than 1000 The latent heat argument supports the view that the molecular weight of the emanation must also be high and of the order of 200 or above It Naturally the theoretical argument based on the value of the latent heat constant fails if it is not legitimate to use the electrometer measurements of Rutherford and Soddy as being equivalent to the ratios of the partial pressures of the radium emanation JAMES DEWAR

Royal Institution October 29

Radium and Geology

FULLER consideration of the experimental evidence on the effects of concentration on the activity of radium convinces me that, on the whole this is certainly against the *a priori* probable assumption that a large part of the activity is not spontaneous I refer more especially to Prof Rutherford's experiment on dilution as touched on in my letter in NATURE of October 25 Other considerations lead to the same view

The conclusion at issue is, however too important to be left on the existing experimental basis J JOLY

Geological Laboratory Trinity College Dublin

The Evolution of the Colorado Spiderwort

UNTIL recently the name *Tradescantia virginiana* of Linnæus was made to include a multitude of forms without discrimination However as we go from east to west we observe a marked change in the spiderworts corresponding with an equally marked change in climate The more eastern forms of moist regions are tall and rank with bright green foliage The true *virginiana* has the pedicels and sepals villous the hairs not glandular and does not in any way suggest a xerophyte In the middle west are two forms *T occidentalis* (Britton) bright green but with narrow leaves and usually smaller flowers the pedicels and sepals with gland tipped hairs and *T reflexa* Raf glaucous the pedicels glabrous the sepals with a tuft of hairs at the apex The latter is more especially southern and is said to extend even to Florida Still further west we find in New Mexico another form *T scopulorum* of Rose slender and much branched glaucous with glabrous pedicels and smooth sepals Still again we have in Colorado a distinct plant which I have named *T universitatis*[1] This is strongly glaucous robust but not very tall pedicels glabrous with a very few gland hairs sepals glandular pilose The leaves are broad (the sheathing bases 12 mm to 13 mm wide) and the flowers are about 35 mm across There is no sign of any tuft of hairs at the apex of the sepals

In all this we have a series of changes not always simultaneous from bright green to glaucous and from simply villous pubescence to gland tipped hairs In some cases the leaves become narrower and the flowers smaller It is easy to see in all this direct adaptation to drier conditions[2] but it is not so easy to determine how it came about or how far it may result from immediate influences modifying individuals of a plastic type At Boulder Colorado the *T universitatis* is a plant of spring and early summer and has the characters just referred to This year however a ditch was dug right through a place where the plants abounded and many of them were covered up by the earth thrown out To day September 30 I find that these plants have managed to sprout through the covering soil and are now in full bloom They are typical except in one conspicuous character—the pedicels and sepals both are profusely gland hairy If one received these specimens with the mere statement that they were gathered on the last day of September noticing the profuse pilosity as well as the unusual time of flowering one would readily take them for a distinct thing

There seems to be some confusion about the plant originally named *occidentalis* by Britton As first described it was said to have narrowly linear leaves and the first locality cited was Wisconsin Rydberg in his recent Flora of Colorado" gives it a quite different range no further east than Nebraska and makes it include the Colorado plants The name must go however with the plant originally described T D A COCKERELL

THE DYNAMICS OF BOWLING.[1]

FOLLOWING up their interesting volume on "Great Batsmen," the accomplished authors of "Great Bowlers and Fielders" have practically completed all that action photography can teach us regarding the methods of great cricketers. The present handsome volume, with its 464 action photographs, registers for all time the successive positions of the body in the act of bowling of some of the most celebrated bowlers of our day, and also certain very characteristic attitudes of a number of our best fielders. From the purely cricketing point of view the book must ever be of the most enthralling interest, not because it establishes any fundamentally new principle in the art of high-class bowling, but because it proves the wonderful variety of method by which different individual bowlers effect practically the same result. The movements of the body, arm, wrist, hand, and fingers are all coordinated to the one end of imparting to the ball a definite combination of translation and spin. It does not always happen that the bowler hits off the exact combination aimed at, but when he does the future progress of the ball through quiet air and off a good pitch is absolutely definite. There is no difficulty in understanding the dynamics of the break; the problem is simply that of a rotating sphere impinging obliquely on a rough surface, and is familiar to every one who has handled a billiard cue with intelligence. The point of interest to the would-be bowler is how it is effected. This is discussed at considerable length in distinct parts of the book contributed by Messrs. F. R. Spofforth, B. J. T. Bosanquet, and R. O. Schwarz. The introductory chapter by the "Demon Bowler" (to whom the book is dedicated) is capital reading. It is indeed rather to be studied than read, and the same remark applies to Mr. Bosanquet's lucid and scientific discussion of the off-breaking leg-break.

FIG. 1.—W. Rhodes at the beginning of his final swing. From "Great Bowlers and Fielders."

At the very outset it is obvious that no bowler can give to a cricket ball anything like the combined velocity and spin which can be so easily communicated to a golf ball or even to a tennis ball. The comparative lightness of the latter enables the player to give it sufficient spin (with velocity) so as to call into action the differential air pressure producing evident swerve. Tait in his discussion of the golf-ball flight showed that this swerving force (which acts at right angles to the plane containing the velocity and the axis of spin) may be taken as being proportional to the product of the translational and angular speeds. He estimated that it might attain a value equal to about four times the weight of the ball. In the case of the cricket ball it is doubtful if the deviating force due to air pressures acting on the progressing and rotating ball could ever become more than a small fraction of the weight. Then as the rotation takes place in all over-hand delivery about an axis which makes at the most a small angle with the horizontal, it is clear that there is very little chance of a cricket ball *beginning* its swerve to right or left for the same reason that a golf ball is sliced or pulled. How, then, is the swerve to be explained? The matter crops up at intervals throughout the book, and is discussed at some length by Mr. Spofforth; but with all due regard to his authority as one of the greatest bowlers of all time, it is difficult to accept his explanation as in every respect sound. He says that "a ball which has check spin (that is, under spin) on it loses it through friction against the air during its flight; at the moment this occurs the ball slips the cushion of air it has made, especially in between the seams. What leads me to this belief is that it is almost impossible to swerve unless the seam of the ball is up and down. The check spin keeps the seam vertical until the air-resistance causes the spin to cease altogether. At this point, especially if the ball has an upward tendency and the earth's power of attraction is asserting itself, the swerve will be great. To swerve the ball must have some spin on it, but not much. If it has great spin it will never lose it in time to swerve, and I maintain that at the actual time of swerving the ball has ceased to spin, or nearly so." Further on he says that he has "never seen any bowler swerve with the wind," that "a bowler swerves more while the ball is new," that he does

[1] "Great Bowlers and Fielders: Their Methods at a Glance." By G. W. Beldam and C. B. Fry. Pp. xv+547; illustrated. (Macmillan and Co., Ltd., 1906.) Price 21s. net.

not believe 'anyone (bowling as is usual twenty one yards or less) can get the swerve unless he over pitches the ball." The facts seem to be that for right or left swerving it is essential to have a cross wind blowing, a long pitched ball, and some initial spin with the seam vertical, but not too much of it. It is difficult to believe that the air's resistance can effectually destroy this spin, seeing that the air has apparently very little effect in cutting down the spin which ultimately produces the break. The very fact

FIG. 2.—J. Tunnicliffe securing a one handed catch high up in the slips. From "Great Bowlers and Fielders."

that the ball is projected with a smaller spin to begin with will mean less effective frictional moment acting on the ball. Stokes in fact agreed with Tait that the frictional decay of spin in the case of a golf ball might be neglected to a first approximation, and we may assume the same for a cricket ball.

There is not the least doubt that spin with the seam vertical must produce vertical swerve, to some extent a downward or upward force acting on the ball in addition to gravity according as there is under spin or over spin. Probably most bowlers have an average amount of spin which they put on the ball. This will give what the batsman regards as the normally pitched ball of that bowler. Suppose this normal spin to be over spin. Then it is clear that if the bowler diminishes the over spin or gives an under spin the pitch (*other things being equal*) will be lengthened, but if the over spin is increased the pitch will be shortened. Again, if the normal spin is under spin, a diminution of that will make the ball appear to drop shorter than the expected normal pitch. This is obviously one way of varying the pitch, and one which must be very deceptive to the batsman. This way of stating it might seem at first sight to be inconsistent with Spofforth's remark that "the vertical spin, unlike others, must have excessive check spin, which naturally impedes the flight of the ball from the start and keeps it back from its true destination." It is difficult to see how check spin can keep the ball back from the start. So far as motion through the air is concerned there will be just as much retardation with the over spin rotation as with the under spin rotation. The word "check spin" is in fact unfortunate, suggesting that it not only checks the progress of the ball after it strikes the ground, and that is the origin of the name, but also that it checks the ball as it moves through the air. In all probability the bowler when putting on excessive check spin projects the ball with a somewhat smaller velocity than the motion of the arm would imply. The hand in fact must get ahead of the ball, as is very clearly indicated in one of the photographs of R. O. Schwarz. With a pronounced under spin a smaller velocity of projection is needed for a given length of pitch than when there is no spin, and the velocity of projection is less than what the motion of the arm would suggest. Hence the feeling of a retarded ball both to the bowler and the batsman. The direct effects of varying spins upon the trajectory as described above are true only when other conditions are the same, such as the velocity of projection and the height of the point of projection; but in giving different amounts of spin to a ball it is evident that these other conditions can not be always the same. The conditions of the problem are indeed difficult to state, and one great merit of Mr. Beldam's action photographs is that they throw so much light on the way in which the ball leaves the hand.

But the outstanding difficulty is to explain the right or left swerve, and the action photographs give little

help here The main fact is that all swervers project the ball with the seam as nearly as possible in a vertical plane In the grip the fingers do not touch the seam, although in some cases the thumb does But evidently there is little purchase on the ball, which is projected with comparatively little spin If cross wind is not absolutely essential it certainly greatly facilitates the swerve With some bowlers the swerve is evident from the start, with others it begins to appear only during the latter half of the trajectory The seam is really a roughened zone on which the air may be supposed to exert a greater frictional force than on the other parts of the ball, especially if the ball be new With seam vertical and a cross wind blowing, certain definite dynamical effects will follow One of these will be a tilting of the axis of rotation, a tilting which will, however, take place very slowly when the spin is excessive This suggests the question does the seam remain vertical throughout the flight of a swerving ball? The point might be settled by bowling a swerving ball against a blackened surface and finding which part of the ball first came in contact with the surface That, however, is outside the purpose of the volume

The questions of swerve and break have much scientific interest, but they cover only a part of the whole, and from a cricketing point of view much might be said, not only as to the excellence of the pictures, but as to the instruction conveyed by them and by the accompanying letterpress Mr Beldam has aimed at getting a succession of positions of each bowler, from the beginning of the final stride before delivery to the follow through after the ball is delivered In a few cases the series begins even sooner Where so much is excellent and characteristic it is difficult to choose but here we have reproduced two pictures which will show to what a high degree of perfection Mr Beldam has carried his photographic art The one represents W Rhodes at the beginning of his final swing and is chosen partly because of the perfection with which the grip of the ball is indicated The other is taken from the last quarter of the book, which treats of fielders and is a remarkably fine picture of J Tunnicliffe securing a "wide, high up right handed catch in the slips" This is one of a series showing Tunnicliffe bringing off difficult catches in most extraordinary attitudes

Like its predecessor, "Great Batsmen" this volume is a treasure-house of portraits of many of the most conspicuous cricketers of to-day It is further beautified by a good coloured reproduction of the portrait of F R Spofforth painted by H S Tuke, A R A

THE POSITION OF AGATHOCLES DURING THE ECLIPSE OF B C 310 AUGUST 15

ON B C 310 August 14 Agathocles left Syracuse by sea, at eight o'clock on the following morning he saw a total eclipse of the sun His exact position is therefore of extreme interest to astronomers Unfortunately, the course that Agathocles steered is not directly stated The present paper is an attempt to piece together the various clues contained in the narratives

We may first briefly glimpse at the way in which Airy handled this question (Phil Trans, 1853, p 188) It appears that on August 20, after a six days' voyage, Agathocles landed in Africa at a place that Airy identifies with Alhowareah Supposing that he went direct, the distance travelled in six days would be 200 miles, if he went round Sicily the distance would be 330 miles Airy therefore marks off on a map thirty-three miles in a southerly direction and fifty-five miles in a northerly direction. He labels these positions as the "possible southern position", and "possible northern position," and he states in the text that the northern position is the more probable, partly because the distance is greater, and partly because the provision ships mentioned in the narrative probably came from Gela in the south

To us, however, it appears totally incredible that Agathocles, after running from a superior enemy for twenty-four hours or thereabouts, should have been within fifty-five miles of his starting point We will now proceed with our own attempt to reconstruct the situation

The first point is that Agathocles started early in the morning, and to that extent had the more time in which to get to a distance from Syracuse This is proved by an expression in the narrative of Diodorus —"After six days and an equal number of nights, as dawn appeared" (ἓξ δ' ἡμέρας καὶ τὰς ἴσας νύκτας αὐτῶν πλευσάντων, ὑποφαινούσης τῆς ἕω) We have no wish to strain this expression to imply that he started at the exact instant of dawn on August 14 It clearly, however, implies that Agathocles was at sea for so great a part of August 14 as to render the phrase "six days and an equal number of nights" more exact than "five days and six nights"

Our second point is that Agathocles had a fair wind We prove this as follows —The Carthaginian fleet was blockading Syracuse, when some provision ships appeared in the neighbourhood The Carthaginians went to attack the provision ships, Agathocles escaped from Syracuse, the Carthaginians left the provision ships and pursued Agathocles, the provision ships then entered Syracuse It must be remembered that warships could be rowed, and that merchant vessels could only sail, and also that so late as the time of Nelson the power of beating to windward practically did not exist The mere fact that the provision ships entered Syracuse therefore establishes the fact that the wind was favourable, both for the provision ships approaching Syracuse and for Agathocles flying from Syracuse, but other considerations will prove the same point The Carthaginians, by leaving the provision ships when they had all but seized them (πλησίον ἤδη τῶν φορτηγῶν ὄντες), clearly had no intention of letting Agathocles escape Before going to attack, the provision ships they probably argued that the occasion would find Agathocles utterly unprepared, and that by the time he had put his men and stores on board they would themselves be back again Now a stern chase is proverbially a long chase (and, moreover, would have taken them out of sight of Syracuse), and the Carthaginians could not have entertained hopes of getting back in time unless the provision ships lay to windward of them Even as it was, Agathocles was ready for his opportunity His men, we are expressly told, had been on board for some days (πληρώσας ἑξήκοντα ναῦς ἐπετήρει καιρὸν οἰκεῖον πρὸς τὸν ἔκπλουν), and he got to sea at exactly the right moment, that is to say, when the Carthaginians had all but reached the provision ships

Agathocles therefore had a fair wind, and to that extent it is the more probable that he was at a considerable distance from Syracuse by the next morning

Two minor points may here be noticed, though they are not essential to our main case When the sixth day dawned Agathocles found himself in the vicinity of a Carthaginian fleet, not necessarily the same one. He rowed hard towards shore, and by virtue of a long start arrived first, although the Carthaginians were rapidly gaining on him, being more accustomed to rowing than the Syracusans (Justin) Possibly,

therefore, Agathocles owed his escape on August 14 to the fact that he could sail instead of row If so, his minimum pace would be seven knots, or otherwise he would have rowed, and the Carthaginians would perhaps have caught him Again, we are ourselves convinced that Agathocles was expecting the appearance of the provision ships It may be that he was merely prepared for any favourable opportunity, but there is much to prove that he laid his plans very carefully He had, for instance, put saddles and bridles on board He could not take horses with him, but he was prepared to use any he might capture on landing On a subsequent occasion, thinking that the appearance of owls (as birds of good omen) would encourage his soldiers, he set some free, which he had evidently provided beforehand (Grote)

We have therefore established that by 8 a m on August 15 Agathocles had been at sea upwards of twenty-four hours, and that he started with a fair wind He clearly did not stand out to sea more than was necessary, for to do so would be to abandon part of his start The last and most important question is, therefore, did Agathocles go north or south?

Our third point is that Agathocles went north Airy has already noted that the provision ships probably came from Gela, on the south coast of Sicily, since that was the only place still, after the battle of Himera two months previously, friendly to Agathocles (Grote) Airy also notes that even 330 miles is a short voyage for six days, and therefore that the longer course is more probable Airy also makes a third point "It is stated by Diodorus that the troops before sailing supposed that they were to make an attack either on Italy or on the Carthaginian part of Sicily, and by Justin, that, while on the voyage, they supposed that they were going on a marauding expedition either to Italy or to Sardinia " The passage in Justin is really stronger than as quoted by Airy, the troops did not realise at the time that it was Africa where they had landed (tunc primum exposito in Africae litore exercitu consilium suum omnibus aperit), they appear to have thought that they were in Italy or Sardinia, and consequently they must have passed through the Straits of Messina, and subsequently kept out of sight of land until Africa was reached

If, as we believe Agathocles had really planned events exactly as they turned out, he would have ordered his partisans at Gela to send provision ships directly there was a strong south wind, and he probably gave them to understand that he would come to their assistance, and that there would be a naval battle, in which the provision ships might turn the scale Agathocles must have had bitter enemies in Gela, as he had just perpetrated an atrocious massacre there, and we may assume that his partisans there were bound to him by self-interest only, and had no idea of being sacrificed to the Carthaginians merely that Agathocles might escape

Enough of his false plans had been allowed to leak out to the Carthaginians for them to suppose that he was coming out of Syracuse to give battle, it was only at the last moment that the Carthaginians, and perhaps also the men of Gela, realised that he was merely bent on escape from Syracuse Meanwhile he had allowed his men to think that they were bound for Sardinia Had they steered south his men would have thought that Agathocles was not acting according to a prearranged plan, but from hand to mouth as best he could If they steered north his men would have felt the confidence engendered by seeing everything going according to the programme If Agathocles had laid his plans beforehand, he would probably have collected information as to currents in the Straits of Messina, and would have known that, in the early afternoon of the day preceding new moon, there is a five-knot current running northwards (Mediterranean Pilot) This current may possibly have contributed materially to his escape, for he seems to have been hard pressed (ἀνελπίστου σωτηρίας ἔτυχε) If he went northward, it certainly adds ten miles to the distance he would otherwise have traversed by the time that he saw the eclipse

P H COWELL

SCIENTIFIC INVESTIGATION IN INDIA[1]

THE Board of Scientific Advice was constituted in the year 1902 by the Government of India as a central authority for the coordination of official scientific inquiry, its object being to ensure that the work of research was distributed to the best advantage, that each investigator employed by Government should confine his researches to the subject with which he was most capable of dealing, and that energy should not be wasted by the useless duplication of work or misdirected by a lack of inter-departmental cooperation It was, more especially, hoped by the Government that the Board would materially assist it in prosecuting research in those questions of economic or applied science which are of direct practical importance, and thus contribute towards the solution of those problems and matters on which the progressive prosperity of the country more especially as regards its agricultural and industrial development, so largely depends

The Board includes the Secretary to the Government in the Department of Revenue and Agriculture which controls and administers the various scientific and semi-scientific departments, and the heads of those departments, including the Surveyor-General of India, the Director-General of Indian Observatories, the Directors of the Geological and Botanical Surveys of India, the Inspectors-General of Forests of Agriculture, and of the Civil Veterinary Department

It advises generally upon the operations of the departments, discusses the programmes of work and investigation of each departmental head submits annually to Government a general programme of research embodying the proposals of departmental heads in so far as their subjects are to be exclusively dealt with in one department and its own proposals when two or more departments are to cooperate, and also at the end of the year prepares a review stating briefly the actual results of the work of investigation carried out during the previous year in the scientific departments The programmes and reviews are communicated through the Secretary of State to the Royal Society, which has selected suitable committees to consider the reports and advise Government chiefly on the scientific problems presented or indicated by the reports

The necessity for some such arrangement has forced itself upon the Government of India with the rapid extension of scientific investigation during recent years Private enterprise in such work is practically nil in India, and hence Government has to initiate all scientific investigation that is necessary for the well-being and progress of the Empire India is at the present stage a country with limited resources, the development of which depends upon the application of modern scientific methods and knowledge to pressing economic problems The heads of Government can gauge the requirements and initiate departments of inquiry and research, and state for

1 Report of the Board of Scientific Advice for India for the Year 1904 5

their guidance the general problems with which they have to deal. In order to control the work of their scientific experts, and to direct it on utilitarian and practical lines, they have found out that it is desirable to obtain the opinion of their scientific officers as a whole, and of a final independent scientific authority, viz., the Royal Society. In this way the Government secures the cooperation of its whole body of scientific officers, and also the execution of the work of research in the most efficient and economical manner, and on the practical lines which it desires. Research is, in fact, directed to practical problems that require early solution, and is not wasted on inquiries which are only of importance from the theoretical standpoint.

The report is full of interest. It shows the wide range of problems with which the departments dealt in the year 1904–5, and the results of their work.

A series of experiments was carried out during the year at the Cawnpore experimental farm similar to those at Rothamsted. It was, for instance, ascertained that of the 43.3 inches of rain which fell during the monsoon period of 1904, 5 inches were required to make up the evaporation during the previous dry period, about 9 inches were taken up by evaporation during the monsoon, 4 inches ran off the surface during a very heavy fall in September, and the remainder, 25.7 inches, percolated. The records also established that the amount of percolation is proportionate to the rainfall, and that the quantity of water lost by evaporation from the soil is greater during the four months of the monsoon than during the eight months of the dry season. These results are in general accordance with the Rothamsted records, and hence probably apply to the whole of the plain of northern India.

The Geological Department issued during the year the results of a special investigation into the Dalhousie earthquake of April 4, 1905. It was one of the most destructive earthquakes which has visited India for many years. At least 20,000 human beings are estimated to have perished. The shock was sensibly appreciable over an area of 1,625,000 square miles. The main focus was at a depth of from eighteen to thirty miles below the surface in the Kangra district. The larger waves reached Bombay and Calcutta at almost exactly the same instant. As both places are at the same distance from Kangra, the rate of transmission in both directions was the same, viz. 1.98 miles per second. The seismograph records of Kodaikanal indicated a speed of 1.95 miles per second, and the Japanese seismographs 2.05 miles. The results hence apparently indicate that the earthquake waves travelled out to the east and south at a rate of almost exactly two miles per second.

The report of the Survey Department is especially interesting. The following extract gives a very brief account of the survey work carried out in Thibet during and after the expedition. "Triangulation was executed connecting Lhasa with India, and fixing all prominent peaks, the country was surveyed and charted on a scale of 4 inches to the mile, the valley of the Brahmaputra was surveyed from Shigatze to its source, the Manasarowar lake region was surveyed, as also the source of the Gartok branch of the Indus and the Thibetan source of the Sutlej. The work was carried out in the face of many difficulties in a country with an average elevation of 16,000 feet and a climate of Arctic severity." One of the interesting results of the expedition was to establish that Everest is, so far as is yet indicated by exact measurement, the highest peak in the Himalayas. Sir Richard Strachey, one of the greatest authorities on Himalayan geography, suggested many years ago the possibility of peaks exceeding 30,000 feet awaiting discovery. All recent investigation appears to establish that it is extremely improbable that there is any peak higher than Everest. It was also ascertained during the Thibetan survey that neither in Nepal nor Thibet is Mount Everest known to the inhabitants by any native name.

The pendulum operations of the Survey of India are furnishing results of great interest. By means of pendulum observations the force of gravity can be ascertained at any place, and as conducted by the survey with the greatest care and delicacy, it can be obtained with a probable error of less than 1 part in 100,000 of its actual value. The earliest observations of this class in India were carried out by Major Basevi upwards of thirty years ago in the western Himalayas. The results of his observations indicated that the force of gravity on the lower Himalayas was considerably less than its value as deduced by geodesists from theory. The deficiency in one case, that of Moré, at an elevation of 15,400 feet, was about 1/2000th part of its theoretical value, and equivalent to the reduction of what may be termed the effective level above the sea of Moré to only 700 feet. It was hence inferred that this deficiency was due to an actual deficiency of matter below, and hence generally that the excess of matter forming the Himalayas is probably, as a whole, compensated by a deficiency of matter in the interior of the earth beneath the mountain mass.

Major Lenox Conyngham recently carried out a lengthened series of pendulum observations. The chief results of his work are that there is a deficiency of gravity (that is, the actual is less than the theoretical value) along and over the outer ranges of the Himalayas. The compensation hitherto assumed to exist as a result of Basevi's measurements is shown by Conyngham's observations to be only partial and not complete. Further south, in the Indo-Gangetic plain, the deficiency disappears and is replaced by an excess. Probably when sufficient data are available it may be possible to formulate a theory of Himalayan structure.

Much valuable work was done during the year in the field of agricultural botany. Amongst the subjects of inquiry was that of the possible deterioration of the jute plant in Bengal. It was ascertained that there is not only no proof of any deterioration, but strong evidence that the plant is now precisely as it was a century and a half ago. The best kinds now, as then, if cultivated liberally, yield excellent crops, and their fibre, if properly extracted, is also excellent. Fraudulent watering in the preparation of the fibre is resorted to with the object of fictitiously increasing its weight for sale. The deterioration of the fibre (not the plant) is due to the fact that the demand for good jute exceeds the supply, and hence that inferior fibre is readily purchased.

As showing the value of the cooperation of the Board of Scientific Advice and the advisory committee of the Royal Society, it is sufficient to mention that they both suggested the necessity for increase of officers in the Geological Department in order to carry out the survey of the geology and mineralogy of Burma. The Government of India accepted the suggestion, and recently sanctioned the addition of four officers to the strength of that department.

The Board is, as shown by the report, doing valuable service in India by coordinating and promoting scientific work, and it is much to be wished that the English Government would adopt some similar plan, and revise the scheme of operations of its chief observatories at Greenwich, Kew, and South Kensington.

NOTES

The Bureau des Longitudes of France has decided to send to Samarkand a scientific expedition to observe the eclipse of the sun which will be visible in Central Asia on January 13, 1907 M Stefanik, astronomer attached to the Meudon Observatory, who accompanied the director Dr Janssen, in the expedition for the observation of the solar eclipse of August, 1905, has been selected as the chief of next year's expedition M Hanski, of the Pulkowa Observatory will join him at Samarkand, and will be in charge of the Russian expedition for the same eclipse M Stefanik, who is now completing his preparations for departure, will take a kinematograph to reproduce the principal scenes of the observation of the eclipse by the French Russian and other missions

Weather prophecy in the United States promises to make a distinct step in advance with the commencement of November Arrangements have been made with the Central Physical Observatory at St Petersburg for reports practically covering the great land area lying between the Russian capital and the Pacific a region embracing nearly one-half the girth of the globe Cable communications with Iceland, together with the facilities now afforded for weather messages by wireless telegraphy, will complete the information for the entire zone of the earth's atmosphere These facilities will enable the U S Weather Bureau to extend considerably the area covered by its present forecasts, and to issue them for a longer period in advance In winter, which is the stormy period of the year, Iceland embraces about the centre of the Atlantic low-pressure area, and the barometer changes experienced will afford much useful information Indian meteorologists have long gauged the importance of the weather conditions over Asia for the framing of long-period forecasts, and a careful study of the minor atmospheric changes over-riding the more permanent seasonal conditions of this vast continent will doubtless aid much in advancing our knowledge of atmospheric circulation

Reference has already been made (October 11, p 591) to the banquet given to Sir William Perkin in New York on October 6 *Science* of October 19 contains a paper read on that occasion by Dr Hugo Schweitzer describing the influence that the discovery of the mauve dye has had upon the progress of chemical science and a report of Sir William Perkin's own account of the discovery of this dye and the development of the coal-tar colour industry started by it

The *British Medical Journal* announces that a congress of practical hygiene will be held in Paris on March 26–31, 1907, under the presidency of Prof R Blanchard The work of the congress, which will deal with food alcoholism, the rearing of children, the workshop, country life, and the colonies, will be distributed among eight sections The general secretary of the congress is M Schaer-Vézinet

Before leaving South Africa, Sir David Gill, K C B, F R S, who will retire in February next after occupying the post of Astronomer Royal at the Cape since 1879, was entertained at a farewell dinner Science, art, politics literature, commerce, and other spheres of human activity were represented, and many testimonies were borne to the services rendered to science and to South Africa by Sir David Gill The Hon E H Walton, in proposing the toast of "Our Guest," referred to the active part taken by Sir David Gill in founding the Association for the Advancement of Science in South Africa, his work in laying the foundations of a complete accurate survey of the Cape peninsula, and his contributions to the progress of astronomical science by observations at the Cape Observatory established by him In his reply, Sir David Gill took the opportunity to insist that all progress in the arts has followed the pursuit of pure science, and incidentally directed attention to his own efforts in organising new work and in urging the Government to provide funds to carry out necessary improvements

The *Home and Counties Magazine* for October contains an article, with portrait on "Peter the wild boy" who was found in the forest of Hertswold near Hanover, in 1725, and was brought to this country by order of Queen Caroline in the following year After ineffectual attempts had been made to get him to speak and to educate him he was ultimately established first at one and then at a second farm near Northchurch Herts, where he died in 1785 The current statements as to his great climbing powers and his habit of going about on all fours were denied by the then headmaster of Berkhamsted Free School to whom Peter was well known Various matters connected with local history, architecture church plate monumental brasses &c form the subjects of the other articles in the same issue

In the course of an address delivered at the eighteenth annual meeting of the Association of Economic Entomologists, and published in Bulletin No 60 of the Entomological Section of the U S Department of Agriculture, Mr H Garman alluded to the prominent position now occupied by the economic entomologist He it is the speaker claimed who has enlisted the attention of the public and educated it to the importance of entomology as applied to agriculture and other human concerns The pure science worker would never have done this, and it thus has happened that the entomologist who was at one time looked down upon by his fellow-worker with something in the nature of disdain has taken first place in the estimation of the general public and demands attention when the recluse laboratory worker gets little consideration And this is as it should be The economic entomologist can claim all entomology as his " The rest of the issue is mainly devoted to an account of the work of the U S Bureau in fighting insects injurious to man and cattle, or harmful to crops and trees in the United States and its dependencies The attention of those concerned may be directed to the fact that on account of preoccupation, the generic term Pyrosoma (see p 17 of the Bulletin) is not available for the organism of Montana spotted fever

Two additions to the literature arising out of the British Association visit to South Africa have recently reached us One is a small illustrated handbook by Dr Haddon F R S published by the Union Castle Company and dealing with the general features of South Africa and his impressions formed during the visit The other is a contribution by Mr C F Rousselet on the Rotifera of South Africa in the Journal of the Royal Microscopical Society for August It contains lists of all the known species of South Africa As the author points out collecting except at such places as the Victoria Falls, was difficult owing to the shortness of the visit and the general dryness of the country, but if one may judge from the large ratio which Mr Rousselet's specimens bear to the total number of recorded species there must be plenty of work for any residents who will search for ponds and ditches in any part of South Africa On the ship, going and coming Mr Rousselet took daily observations of the plankton contained in the hose-water

"EDIBLE Earth in New Guinea" is the title of a communication by Mr W Meigen published in *Briefe der Monatsberichte der deutschen geologischen Gesellschaft* (1905, pp 557–564) The earth in question is found on the east side of New Mecklenburg, where it is associated with decomposed coral, its main constituents are oxides of silica and aluminium, there is a smaller quantity of ferric oxide and traces of other substances, including ammonia Mineralogically, the earth is composed of kaolin, hydrargillite, and ferric oxide, it is a fatty clay of yellowish colour not unpleasant to the taste and composed of very small particles It is used for medicinal purposes and may well counteract the laxative effects of the fish diet of dwellers on the coast The article mentions the more important previous contributions to the discussion of the question of edible earths, of which, however, but few analyses have been published A recent paper was noticed in NATURE of September 27 (p 543), in vol xxxiii of the Journal of the Royal Society of New South Wales was published the analysis of some kaolinite from Fiji

THE Bulletin of the Johns Hopkins Hospital for October (xvii No 187), in addition to articles of medical interest, contains an account by Mr D I Macht of Moses Maimonides, a celebrated Jewish philosopher of the thirteenth century, who was physician to the Sultan Saladin and his successor, and the author of many religious philosophical, and medical works In his "Ethics" a complete system of practical hygiene is given which would well compare with the most recent text-books on the subject, lack of exercise, over-eating alcohol and excess are summarised as the causes of most diseases Dr T R Boggs describes a simple method for the quantitative estimation of the proteids in milk The diluted milk is precipitated with phosphotungstic acid in hydrochloric acid solution, and the volume of the precipitate is read off in an ordinary Esbach albuminometer tube as used in wine analysis The method is accurate to within 0 3 per cent to 0 7 per cent, according to controls made by Kjeldahl determinations

As agriculture in the Virgin Islands is dependent upon small cultivators progress is hampered by the want of capital In the annual report for 1905–6 of the experiment station maintained at Tortola, the curator, Mr Fishlock, notes that the peasants are gradually realising the advantage of planting such permanent crops as cacao, limes and rubber The department also fosters cotton cultivation by supplying seed, buying seed-cotton, and preparing the lint for market

THE July number of the Trinidad Bulletin contains the annual report for the past year, by Mr J H Hart on the Botanical Department Seedling canes, rubber, and cacao form the largest items under plant distribution, there was also a considerable demand for young trees of Honduras mahogany, *Mimusops globosa*, that furnishes *balata* and *Cedrela odorata*, the West Indian cedar With the view of popularising its cultivation, a large number of plants of *Coffea robusta* was given away In a note on the nests of Trigona bees it is observed that the peculiar trumpet-shaped entrance is connected with the danger to returning bees of being caught by a spider that lurks near the opening

THE second number of the Memoirs of the Department of Agriculture in India is devoted to the subject of Indian wheat rusts Three distinct species, *Puccinia graminis*, black rust, *Puccinia glumarum*, yellow rust, and *Puccinia triticina*, orange rust, are commonly found It was observed in 1904 that the first was most rampant in Central India, while the latter two predominated further north, and therefore nearer the district where barberries are found The authors Mr E J Butler and Mr J M Hayman, have at present no explanation to offer for the origin of the disease year by year The results obtained by inoculating barley with rust spores taken from wheat plants and *vice versâ* show a considerable degree of specialisation, as very few of the inoculations succeeded

THE superintendent of the Indian Museum, Calcutta, mentions in his annual report for the year 1905–6 that a number of Tibetan and Bhutanese specimens, chiefly robes, brass ware, and religious objects, was added to the art and ethnological collections, also various agricultural instruments from Assam The report of laboratory work by Mr D Hooper contains, as usual, several interesting analyses From the shoot of the common bamboo a food product is prepared, known in Assam as *gass-tenga*, that is eaten with rice, this contains an acid similar to aspartic acid that is probably derived from asparagin Specimens of the bark of *Picrasma javanica*, used by the Karens as a febrifuge, yielded a bitter principle allied to quassiin The analyses of latices from a number of different species of Ficus show that of those examined *Ficus elastica* alone furnishes rubber of commercial importance

ATTENTION is directed in the Journal of the Society of Arts (vol liv, No 2812) to the soda lakes of Mexico on the great desert south of Yuma These vast lakes of crystals of carbonate of soda are within 3000 yards of the sea They are the property of the Mexican Government, and it is believed that they may become sources of enormous income to the country

THE British Commercial Agent in the United States reports that the plan of storing coal under water is being adopted at a new plant west of Chicago Twelve large cement-lined pits have been constructed with a bottom of clay soil Their storage capacity is 14 000 tons A 12-inch water pipe opens to the pits near the top, so that the coal can be flooded when required

IN the *Engineering Magazine* (vol xxxii, No 1) Mr Alfred Sang urges the practical value of industrial museums as exemplified by the Conservatoire des Arts et Métiers in Paris, and what was originally the Patent Office Museum at South Kensington While satisfactory results must depend upon a board of management composed of experts in the various branches of science and of industry represented, the author gives examples of exhibits that would prove of special benefit to students

IN the Journal of the Franklin Institute (vol clxii, No 4) Prof Alfred J Henry, of the U S Weather Bureau, gives an account of weather forecasting by synoptic charts. The method is based on two well-established facts, the general eastward drift of the atmosphere in temperate latitudes in the northern hemisphere, and the close relation that subsists between the weather and the distribution of atmospheric pressure Within recent years there has been an appreciable gain in the accuracy of the forecasts The period covered by the forecasts has been extended from eight to forty eight hours, and instead of forecasts expressed in very general terms for large areas, definite forecasts are now made for all the larger towns and for each of the States and territories The most important gain however, is in the adaptation of the forecasts to the needs of special industries, the perfection of the system of flood warnings, and the general improvement in the warnings of severe storms and cold waves

THE second part, dealing with labour, of the General Report on Mines and Quarries, has been issued by the Home Office as a parliamentary paper (Cd 3179, price 10d) It shows that the total number of persons employed at British mines and quarries in 1905 was 982,343, of whom 887,524 were employed at mines and 94,819 at quarries During the year, 1103 separate fatal accidents occurred at mines and quarries, causing the loss of 1304 lives Compared with the previous year, there is a decrease of fifty-five in the number of fatal accidents, and an increase of 102 in the number of lives lost The general death-rate from accidents at mines was 1 358 per 1000 persons employed Of the fatal accidents at mines, 44 0 per cent were caused by falls of ground Five fatal accidents were caused by the use of electricity underground A very unusual accident is reported at Llanhilleth Colliery, where one man was killed and six men injured by the sudden blast of air caused by a fall from the side of a cavity Some interesting statistics are given showing that gunpowder constituted more than 67 per cent of the total weight of explosives used in collieries About 30 per cent of the weight used consisted of permitted explosives, those most largely used being bobbinite, saxonite, ammonite, roburite, and westfalite Other statistics show that there were 295 collieries where coal-cutting machines were at work, the total number of machines being 946 The total quantity of coal obtained by the aid of these machines in 1905 was 8 102,197 tons

WE have received from the director of the Geological Commission Cape Town, South Africa, the first separately issued sheet of the geological map of Cape Colony The geology is by the director Mr A W Rogers Mr E H L Schwartz, and Mr A L Du Toit The colour printing is clear and there is not too much detail The size of the imprint is 21½ inches by 27 inches, the scale is 1 inch = 1600 Cape roods which is equivalent to about 3 7 miles to the inch The commission is to be congratulated upon the production of an excellent map

PART 1 vol xxxiv of the Records of the Geological Survey of India contains two reports upon occurrences of coal, one in the foothills of Bhutan by G E Pilgrim, the other in the Kotli Tehsil of the Jammu State (Dandli coalfield), by C M P Wright Mr Pilgrim contributes also some notes on the geology of Bhutan, Dr Diener supplies notes on some fossils from the Halorites limestone of Bambanag Cliff, in which he describes a new genus, Martolites near to Celtites of Mojsisovics, and a new species of Halorites *H trotteri* He also describes the Upper Triassic fauna of Pishin In the appendix, analyses are given of three samples of muds from the Travancore coast

THE *Rendiconto* of the Bologna Academy is sometimes rather late in appearance, but the three last numbers (1902–5) contain one or two papers of more than passing interest Prof Guido Tizzoni in the name of Dr Bongiovanni read a note on the influence of radium on the virus of rabies It was shown that radium rays rapidly destroyed the virus, both when contained in tubes and when applied to animals within an hour or so of their infection, and methods were found by which animals already suffering could be cured with certain results The previous number (vol viii) contains an account of the botanical results of the two scientific expeditions to Montenegro organised by the Italian Government in 1902 and 1903

A PAPER by M Edouard Collignon on the solution of the cubic equation is published in abstract in the Proceedings of the Edinburgh Mathematical Society, xxiv (1906) It is based on the property that every cubic can be reduced to one of the three forms x^3 = constant or $x^3 \pm x$ = constant By tabulating the values of x^3+x and x^3-x for different values of x, the roots may be found in the same way that antilogarithms are taken from a table of logarithms The properties of the roots are discussed in connection with the graphs of $x^3 \pm x$ and it will be noticed without going further into the details of the paper that the turning points of the curves determine very simply the conditions for three or one real roots The author examines how far a similar method is applicable to curves of higher degree

WE have often directed attention to the excellent series of monthly volumes entitled the *Practical Photographer* edited by the Rev F C Lambert, and published by Messrs Hodder and Stoughton It was found that the size of page was rather too small to show off effectively the fine reproductions from well-known photographs which were a distinct feature of the series In April last the size of page was doubled and since that date we have received the monthly issues which indicate the wise policy of such a change The present series is now termed the *Practical and Pictorial Photographer*, and is issued as a library series the price being the same as the previous volumes namely one shilling The October number is full of interesting matter and is illustrated by seventeen reproductions

FROM Messrs Newton and Co we have received a simple convex lens of 2 5 inches diameter having a focal length of about 6 feet On a small portion of the periphery of the lens is firmly sealed a metal base carrying a small screw which enables the lens to be easily fixed to the end of a walking stick or umbrella The lens and attachment are enclosed in a neat leather case, which can be comfortably carried in the waistcoat pocket This "unilens," which has recently been patented by Major Baden Powell, serves the purpose of a low power pair of opera-glasses without the trouble of carrying them The use of such a lens in this manner is not new, but the present form of mounting will make it of more general service than hitherto Those who possess approximately normal eyesight would find great comfort in having ready at hand such an easy means of magnifying distant objects When placed on the end of a stick and the latter held out at arm's length, the object observed is seen at the greatest magnification and even at less distances the object is always in focus, but not so much enlarged The simplicity and portability of this "unilens" should find favour with many who are in search of a pocket telescope

THE first part, comprising no less than 1437 titles of a valuable catalogue of important works, chiefly old and rare on mathematics, astronomy physics, chemistry and kindred subjects has just been issued by Messrs H Sotheran and Co This "Bibliotheca Chemico-mathematica" will be completed in three or four parts which will be issued at intervals of a few months each The part just received has on the first page works by Ernst Abbe, Abel, and Abercromby, and the last titles are of works by Galileo Among numerous other volumes and memoirs included in the catalogue are a copy of the very rare first edition of the great work of Copernicus "De Revolutionibus Orbium Cœlestium" (1543) which commenced a new epoch in the history of astronomy the first

printed edition of Euclid's "Elementa Geometriæ" (1482) the first edition of de Caus's "Les Raisons des Forces mouvantes" (1615), to which, according to Arago, is due the invention of the steam engine, Daguerre's description of his invention of the Daguerreotype process of photography (1839), and the earliest works on ballooning. Bibliophiles and librarians looking out for scientific works of great rarity and interest, or for volumes of Proceedings of scientific societies and standard books on the exact sciences, will find it an advantage to consult the interesting catalogue, the first part of which Messrs. Sotheran have just published.

MESSRS. GEORGE PHILIP AND SON, LTD., will shortly issue a novel perpetual calendar invented by the Rev. J. W. Wiles. It is claimed that by a simple arrangement the calendar will show the day of the week of any day in any year from the beginning of the Christian era to the end of time.

MR. W. A. SHENSTONE, F.R.S., has revised, and in some instances amplified, the essays he recently contributed to the *Cornhill Magazine*, and they will be published by Messrs. Smith, Elder and Co. to-morrow under the title of "The New Physics and Chemistry: a Series of Popular Essays on Physical and Chemical Subjects."

MESSRS. ARCHIBALD CONSTABLE AND CO., LTD., will publish very shortly a volume by Prof. E. Ray Lankester, F.R.S., entitled "The Kingdom of Man," containing a statement of the present position of scientific knowledge and the promise of the future.

THE second quarterly number of *Science Progress in the Twentieth Century* has now been published by Mr. John Murray. The ten articles included in this issue of the new scientific quarterly review range over many departments of science, and should appeal to a wide circle of readers.

THE first parts of two works of science which are being published serially by Mr. Fritz Lehmann, Stuttgart, have been received. "The Macrolepidoptera of the World" by Dr. Adalbert Seitz is to be completed in 100 parts, and "Das Mineralreich" by Dr. Reinhard Brauns, in seventy-five parts. Both works are illustrated by excellently produced coloured plates. Messrs. Williams and Norgate are the agents of the publishers in this country.

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN NOVEMBER:—

Nov. 5	11h. 24m. to 12h. 34m.	Moon occults ν Geminorum (mag. 4·1).
9.	9h.	Mercury at greatest elongation (E. 23° 0').
10.	12h. 17m. to 13h. 33m.	Transit of Jupiter's Sat. IV. (Callisto).
11.	7h. 15m. to 10h. 15m.	Transit of Jupiter's Sat. III. (Ganymede).
15.	Saturn.	Major axis of outer ring = 41"·27, minor = 4"·64.
,,	9h. 33m.	Minimum of Algol (β Persei).
15.	Venus.	Illuminated portion of disc = 0·070, of Mars = 0·959.
15–16.		Epoch of November Leonids (Radiant 151° + 23°).
17–21.		Epoch of November Andromedids (Radiant 25° + 43°).
18.	6h. 21m.	Minimum of Algol (β Persei).
18.	10h. 45m. to 13h. 46m.	Transit of Jupiter's Sat. III. (Ganymede).
19.	5h. 30m. to 6h. 34m.	Moon occults σ Sagittarii (mag. 3·9).
25.	14h. 11m. to 17h. 12m.	Transit of Jupiter's Sat. III. (Ganymede).

GREENWICH OBSERVATORY AND THE POWER STATION.—At the meeting of the Astronomische Gesellschaft recently held in Jena (September 12–15) Dr. Foerster directed attention to the erection of the large generating station near to Greenwich Observatory and the consequent interference with the work of the institution. After Prof. Dyson had described the unfavourable position in which the observatory is situated, a resolution having the following effect was passed:—That the convention of the International Astronomische Gesellschaft, meeting in Jena, in view of the communication made in the latest report of the Greenwich Observatory, expresses the hope that the loss which would be occasioned if the observatory were removed may be averted. The resolution also expressed the hope that as Greenwich has succeeded in establishing itself as the standard place, all future proposals to remove it may likewise be averted (*Astronomische Nachrichten*, No. 4127).

LUNAR CHANGES.—In No. 588 of the *Astronomical Journal* Prof. W. H. Pickering discusses Mr. Stebbins's observations of the lunar crater Linné, made during the eclipse of the moon which took place on February 8, 1906, and compares them with the similar observations made at the same time by Prof. Frost. Although some slight doubt exists as to the precision of one or two of Mr. Stebbins's measures, the curve showing the change in diameter of the spot surrounding Linné, according to his observations, agrees in general with the similar one obtained by Prof. Frost. Both show a substantial increase in the diameter immediately after the passing of the earth's shadow. Prof. Pickering ascribes this increase of diameter to the deposition of hoar frost, or something analogous to it, caused by the drop in temperature consequent upon the screening off of the sun's rays by the opaque body of the earth. This phenomenon has now been observed by six observers working quite independently, several of whom were originally prejudiced against it; therefore Prof. Pickering considers that it may be accepted as confirmed.

The variation of the diameter of the spot during the ordinary course of lunation has similarly been confirmed by several observers, one of whom, Dr. C. W. Wirtz, discusses his observations at some length in No. 4118 of the *Astronomische Nachrichten*.

ECLIPSE OBSERVATIONS.—In No. 9, vol. xxxv., of the *Memorie della Società degli Spettroscopisti Italiani* Prof. Riccò concludes his account of the eclipse observations made by the Italian expedition to Alcala de Chivert in August, 1905. Among other matters he discusses "white prominences," and describes those seen during the eclipse in question as faint and indistinct, especially in the lower parts, and appearing as little more than a whitish shadow projected on to the background of the corona. He also suggests that these objects are in nature somewhat of an intermediate stage between the prominences and the true coronal streamers.

Estimating the height of the various layers of the solar atmosphere by two independent methods, Prof. Riccò found that that which he calls the "reversing layer" or the stratum producing the so-called "flash spectrum," extends to some 3" or 2000 km. (1250 miles). That part of the chromosphere which emits D$_3$ and F especially has a height of about 7" to 9", whilst the calcium vapours of the chromosphere extend to about 15" from the base. Photographs taken on special plates with a prismatic camera show that the maximum brightness of the continuous spectrum of the corona occurs in the yellow and red regions.

THE ZODIACAL LIGHT.—During the past summer Prof. Barnard, at the Yerkes Observatory, made a number of observations of the zodiacal light, the results of which he now publishes in No. 2, vol. xxiv., of the *Astrophysical Journal*. On June 22 he paid special attention to the phenomenon, and found it to be much more extensive than he had previously supposed. He concludes that the light extends at least 65° north and south of the sun (assuming the southern extent to be the same as the northern), a value considerably larger than that arrived at by Prof. Newcomb, observing in Switzerland, in the summer of 1905.

THE MIRA MAXIMUM OF 1906.—In No. 4110 of the *Astronomische Nachrichten* Prof. Nijland publishes the results of his observations of Mira made during the period August 24, 1905, to February 24, 1906. The curve accompanying the paper shows that a sharp maximum occurred on January 3, when the star's magnitude was 3·9. This was preceded by a very flat minimum of about the ninth magnitude, extending from the commencement of the observations until November 9, 1905, and then a steep ascent to the maximum. The lowest magnitude, 9·05, occurred on September 23, 1905.

METEOROLOGY OF THE NILE VALLEY.[1]

THE Egyptian Survey Department, constituted some years ago, is adding largely and rapidly to our knowledge of the hydrography, geology, and meteorology of the Nile basin. The director-general, Captain Lyons, R.E., has prepared and issued a monograph dealing very fully with the physiography of the Nile basin. In this work, which was reviewed in NATURE of September 6 (vol. lxxiv., p. 461), he combines the results of former observers and investigators with the data accumulated during the past ten or twelve years by his department. It is a storehouse of information relating to that most remarkable, and until recent years most mysterious, of rivers.

We propose to give a brief statement, based on the information contained in the monograph, of the more important features of the meteorology of the Nile Valley and their relations to the physiography of the whole area.

The river obtains its supplies from two collecting areas, one the equatorial lake plateau (between lat. 5° S. and lat. 5° N. and long. 28° and 35° E.), and the second the Abyssinian mountain and plateau area (between lat. 7° N. and 14° N. and long. 35° and 40° E.).

The former is the larger catchment basin, and includes the Victoria, Albert Edward, and Albert Lakes, which serve as reservoirs to store the rainfall of the whole region. The Victoria Lake (equal in area to Scotland) is about 4000 feet above the sea, and is slightly lower than the mean level of the plateau. The ground rises slightly to the south and east, and rapidly to the west to the elevated peaks of Ruwenzori, which separate it from the rift valley, in which are situated the Albert Edward and Albert Lakes connected by the Semliki River. The catchment area of the Victoria Lake is only of comparatively small extent, not more than twice the area of the lake, the level of which hence varies very slightly with the season. The Victoria Nile, which issues from the north of the lake, is precipitated over the Ripon Falls, and thence passes over flat marshy ground to the Choga Lake Swamp, and descends by a series of rapids and finally by the Murchison Falls, to the lower level of the Albert Lake at its northern extremity in lat. 2½° N.

The Albert Edward and Albert Lakes, with their tributaries, appear to collect a larger volume of water than the Victoria Lake. The Victoria Lake discharges by the Victoria Nile a nearly constant amount averaging 500 cubic metres per second, and the Albert Lake amounts varying between 500 and 1100 cubic metres per second.

The discharge of the lake system is carried off northwards from the Albert Lake by the Bahr-el-Jebel or Albert Nile, as it is called by Sir William Willcocks. It descends rapidly from a level of 2300 feet to 1500 feet at Gondokoro (lat. 5° N.) in a narrow channel with numerous falls and rapids, and thence to Lake No (lat. 9½° N.) through an extensive flat and swampy region. It is joined at Lake No by the Bahr-el-Gazal, and about eighty miles further down stream by the Sobat. The former drains a large portion of the Soudan, its head-waters being chiefly in the equatorial belt. The Sobat is formed partly by drainage from the same belt and partly from the southern face of the Abyssinian plateau.

Between Lake No and Khartoum the main stream is now known as the White Nile. The discharge of this river below Lake No varies to a slight extent during the year, and averages only 350 cubic metres per second, and hence considerably less than the supply passing into the river from the Albert Lake. The difference represents the loss by evaporation in the extensive swamp region through which these streams flow. That of the Sobat is only considerable during the rainy season, from April to December, ranging between 380 cubic metres and 1470 cubic metres per second. The White Nile below the junction of the Sobat (lat. 9½° N.) to Khartoum (lat. 15½° N.) receives no affluent, and flows in a broad valley as a wide stream of moderate velocity. This part of the Nile plays a subordinate but important *rôle* with respect to the Nile floods. From May to September the flood water brought down by the Sobat River is ponded up or held back in this reach of the Nile, and hence does not contribute to the Lower Nile flood. Captain Lyons states that this action stores up an average of about 1500 million cubic metres from the Sobat flood, which is supplied to the Nile in October, November, and December, thus prolonging the period of the Nile flood, and delaying the fall of the Nile to its low-water stage.

The main flood water of the Nile is brought down by the Blue Nile and the Atbara from the Abyssinian plateau. The rainfall occurs between June and September, and is immediately discharged down the hills into the valleys, the greatest portion down the Blue Nile, which joins the White Nile (there forming the Nile) at Khartoum. The maximum flood of the Blue Nile is about 12,500 cubic metres, and of the Atbara 5000 cubic metres, per second.

The Nile flood proper is hence due solely to rainfall in the Abyssinian and adjacent Soudan area. It commences in June, and reaches its maximum about the end of August or beginning of September. The maximum height of the Nile flood, or the total discharge during the flood period, may hence be accepted as a measure of the total rainfall over that area, just as the variations of the Victoria and Albert Lakes represent the seasonal variations of the rainfall in their catchment areas.

The Nile below the junction of the Atbara (lat. 18° N. to lat. 34° N.) receives no affluents, and flows in a comparatively narrow valley, over which the flood waters with their rich alluvial contents are distributed by means of a vast system of canals.

The Nile basin may hence be divided into three areas or regions not differing greatly in breadth from south to north. The most southerly is the equatorial lake belt between lat. 5° S. and 5° N., an intermediate region between lat. 5° N. and lat. 18° N. includes the Soudan and Abyssinia, and the northerly region comprises the lower Nile basin from lat. 18° N. to the Mediterranean in lat. 34° N. The low river supply (January to May) is chiefly due to discharge from the equatorial lake area, and the summer flood supply to discharge from the Abyssinian region.

The following gives a sketch of the more important features of the meteorology of the Nile basin based on the important information and data of Captain Lyons's monograph.

Temperature is remarkably uniform in the equatorial lake region. Thus at Entebbe, on the north shore of the Victoria Nyanza, it ranges only between a mean of 72°·7 in January and 70° in July. In the Nile basin north of about lat. 5° N. temperature is lowest in January, and attains its maximum in May in the southern half of the valley south of Khartoum, and in July in Nubia and Egypt. The annual range of temperature increases northwards from the equatorial belt to northern Egypt. The greater part of the Nile basin is within the tropics, and is throughout the whole year characterised by high temperature. That portion of it between lat. 15° N. and lat. 18° N. (in which are the meteorological stations of Khartoum, Berber, and Dongola) is the hottest and driest area in the Nile basin. It has an elevation of about 1200 feet. To the south is the comparatively damp and cooler region of the Bahr-el-Gazal, the Albert Nile, and the lake plateau, whilst to the north the valley descends slowly to the relatively cool Mediterranean coast. This—the Soudan hot area—is one of the hottest regions in the world. The following gives a comparison of the mean monthly maximum temperature of Berber in that area, and of Jacobabad, the hottest station in India, and also of Massowa, on the Red Sea, in the same latitude as Berber:—

[1] "The Physiography of the River Nile and its Basin." By Captain H. G. Lyons, R.E., Director-General Egyptian Survey Department.

Mean Maximum Temperature

	Berber, Lat 18° N	Jacobabad, Lat. 28 N	Massawa, Lat. 15 N
January	86.7	73.6	84.2
February	90.0	77.9	85.3
March	96.6	91.1	87.1
April	106.0	103.1	90.5
May	110.5	111.6	94.5
June	112.1	112.7	99.5
July	108.5	107.8	101.6
August	110.3	103.8	101.5
September	108.5	103.5	97.7
October	104.0	98.6	95.0
November	96.0	86.8	89.6
December	89.6	76.7	86.9

The data show that at the hottest period from May to September, the high-temperature conditions are as intense in the Soudan hot area as in Upper Sind, and are more prolonged and persistent This hot area plays a very important part in the meteorology of the Nile basin It is throughout the whole year much hotter than Lower Egypt The difference between the mean day temperature at Berber and Alexandria increases from 8° in January to 16° in April and May It thence diminishes under the influence of the monsoon rainfall in the Soudan region to 8° in August and increases to a second maximum (12°) in November It is undoubtedly due to the presence of this permanent hot area in the central Nile basin that northerly winds prevail almost continuously in the northern half of the basin (*i e* north of Berber) The Massawa data also indicate that the hottest portion of the Red Sea is from 10° to 16° cooler during the day hours from March to October than the land area to the west As the width of the Red Sea in lat 15° to 20° N is about 300 miles, it is evident that the presence of this relatively cool area will modify considerably the air movement and pressure distribution in the adjacent land areas, more especially the Soudan comparatively low-lying area.

Much less is known of the pressure distribution than of temperature in the Nile basin Barometric observations are being taken at a considerable number of stations When the elevations of the observing stations have been accurately determined by the Survey Department, it will then be possible to give, for the first time, a satisfactory statement of the changes of the distribution of pressure during the year It is to be hoped that this information will be available in Captain Lyons's monograph on the meteorology of the Nile basin which we believe he has under preparation Comparison of the temperature conditions of northern India and of the Nile basin suggest the probable pressure scheme Pressure in January and the following three or four months is probably lowest in the interior regions of Africa to the south of the equator An independent local low pressure begins to form in the Soudan hot area in March, and intensifies to some extent in April and May This low-pressure area limits the advance of the monsoon winds in that region in the same manner that the low-pressure area in Baluchistan and Sind and the Himalayan mountain barrier, limit the northward extension of the south-west monsoon winds in India During the period from June to September an extensive low-pressure area extends from the Soudan across south-west Asia to Upper India but it is probable that the Soudan depression, due to the local thermal conditions, maintains an independent existence from the Upper India depression and is separated by a belt of somewhat higher pressure across the Red Sea This is not confirmed as yet by observation Captain Lyons however indicates in the chart of the mean distribution of pressure in northern and central Africa in July his conviction that a local belt of low pressure stretches across central Africa between lat 12° N and 18° N This either fills up in October and November or is transferred southwards

The air movement in the Nile basin is on the whole comparatively simple It is almost continuously from north to the north of lat 17° or 18° N (Berber) and is hence a drift up the valley due to permanent temperature and pressure differences between the east Mediterranean and Upper Nile valley Also in the extreme south of the basin (in the basin of the Victoria and Albert Lakes) it is, so far as is indicated by the available data, almost equally persistent, but from the opposite direction, that is, from south and south-east That region is hence, during nearly the whole year, within the sphere of the south-east trades. The movement is apparently for a short period in the early months of the year light, variable, and irregular, but chiefly from north

The air movement in the intermediate region between the equator and lat 16° N to 18° N is typically monsoon During one period of the year dry land winds (from the north) prevail, followed during the remainder of the year by humid oceanic winds (from south or west) The influence of the Soudan hot area begins to be shown in March, and winds alternate between northerly and southerly directions in April and May Thus at Khartoum the percentage of steadiness decreases from about 90 per cent in January to 40 per cent in May In the beginning of June a change similar to that occurring in India in that month is initiated Steady winds, the continuation of the south-east trade winds, which have previously given heavy rain to the equatorial lake area, prevail during the next three months The direction of the air movement rapidly changes in proceeding northwards from south to west, determined by the position of the Soudan low-pressure area and action due to the earth's rotation The current hence advances directly to the Abyssinian mountain or plateau area, the axis of which runs due north and south, its forced ascent over which gives rise to the heavy precipitation over the greater part of the plateau No rain falls at this time in the Red Sea coast districts on the lee side of the plateau The plateau hence plays (but much more completely) the same part for the Abyssinian branch of the south-west monsoon current that the West Ghats play with respect to the Bombay branch This movement holds steadily until September, when the monsoon current contracts southwards and light, northerly winds extend slowly to the neighbourhood of the equator There is hence a clearly marked monsoon alternation of winds and of season (dry and wet) in the intermediate area between lat 5° N and lat 18° N

The distribution of the rainfall in the Nile basin is very clearly exhibited in a series of monthly charts in Captain Lyons's monograph A chart showing the amount and distribution of the average annual rainfall would have been a useful and valuable addition to the series Charts of annual or seasonal rainfall are, as a rule even more valuable for comparison than charts of monthly rainfall

The air movement has shown that the Nile basin may be divided meteorologically into three areas viz the area of dominant northerly winds (north of lat 17° N), the area of alternating monsoon winds between lat 17° N and the equator, and the area of dominant south-easterly winds south of the equator The rainfall differs greatly in its characteristic features in these three areas In the northerly region it occurs during the winter months, as in Syria, the Euphrates valley, and the Iran plateau, and is small and very variable in amount The average annual fall at Alexandria and Suakim is about 5 inches, at Port Said 2 inches, and at Suez ½ inch In the intermediate monsoon region practically no rain falls from November to April Thunderstorms occur in May, chiefly in the southern districts, and frequent heavy rain from June to September or October according to position The rainfall is heaviest on the western and central portions of the plateau In the Himalayas the rainfall is, as a rule, heaviest at an elevation of about 4000 feet The Abyssinian data are too scanty to show whether there is any line of maximum rainfall lower than the level of the interior plateau or higher mountain ranges, where the highest elevations exceed 15,000 feet

The precipitation in the equatorial lake region has a double maximum and minimum in its annual variation, related, as Captain Lyons points out, to the apparent movement of the sun The rainfall is small in amount during the period of heavy rainfall in the monsoon region from June to September It is heavy from October to December, and again in March and April, and is light to moderate during the intervening months of January and February, and moderate in May

The following summary of the annual rainfall in the Upper Nile basin is taken from Sir William Willcocks's "Nile in 1904." In the catchment basin of the Victoria and Albert Lakes, the mean annual rainfall may be taken as 50 inches, with large fluctuations between good and bad years; over the Albert Nile region it is about 40 inches, with severe droughts occasionally and excessive rain in some years In the catchment basin of the Sobat River it probably averages 40 inches, and in that of the Bahr-el-Gazal region 30 inches The rainfall over the Abyssinian plateau may be taken as 50 inches, and in the lower reaches of the Blue Nile and Atbara 30 inches These are undoubtedly rough estimates, but, so far as can be judged from the exact data given for a number of individual stations in Captain Lyons's work, they are approximately correct values They also indicate that the mean annual rainfall over the Upper Nile basin differs little from 40 inches This is a somewhat remarkable result, as it agrees closely with the average rainfall in India, which, according to Blanford, is 42 inches

The rainfall in the equatorial lake belt resembles in its seasonal distribution that of Ceylon, and that of the intermediate region (the Soudan and Abyssinia) that of western India In western India, as in the East African monsoon region, the cool and dry season is rainless, with clear skies and light to moderate land winds The rains in each agree in period, in the comparative suddenness of the change from the dry to the wet season, in the occurrence of almost daily heavy rainfall, and also in the rapid withdrawal of the humid currents at the end of the season The meteorological data indicate clearly that the rainfall in both areas is due to the rapid extension of the south-east trade winds northwards from the equatorial belt at the same critical epoch, and probably under the same general conditions There is one very important difference The monsoon current in the Nile basin does not extend beyond lat 16° to 18° N, being bounded to the north, not by a range of mountains, but by an area of permanent low pressure during the season, due to thermal actions It curves rapidly from south to west, and is hence determined directly to the western face of the Abyssinian plateau and mountain masses which in their highest points attain an elevation of 15,000 feet The Bombay current in India extends as far northwards as the East Punjab (lat 30° to 35° N) where its further progress is barred by the Himalayas The Abyssinian plateau exhausts the humid current much more completely than the West Ghats as the rainfall at Massowa and other towns on the Red Sea to the east of the plateau is practically nil

It would be interesting to determine whether the humid current is converted into a vertical movement over the plateau or whether it continues to march eastwards, and perhaps to contribute to the monsoon rainfall (of the same period) in the mountain region of Yemen, in south-west Arabia

Captain Lyons has devoted considerable attention to the question of the variations of the Nile flood, and hence of the rainfall in the Nile basin, from year to year The data show that very large variations occasionally occur amounting to ±35 per cent of the mean He infers from the data of years that they do not exhibit any regular cyclical variation, and hence that they cannot be directly correlated with the eleven-year sun spot period or the thirty-five-year Bruckner period

It is now, we believe, fully established that Abyssinia, India, and Burma, with the Malay Peninsula, receive nearly the whole of their rainfall from the same vast reservoir and evaporating area, the Indian Ocean and seas and under the same general meteorological conditions and by means of the same general air movement These facts, on the one hand, indicate a probable similarity or parallelism of the seasonal variation of rainfall in all three areas due to general conditions in the contributing oceanic area, and, on the other, an unequal and unlike variation due to variation of local conditions in the three large areas of distribution, also as the rainfall of the Abyssinian plateau is due to the same branch of the monsoon current as that of western India, any parallelism of variation is more likely to be exhibited by these two regions than by either compared with Burma or north-eastern India (dependent on the Bay monsoon current) The actual variation in any one year will hence be due to the resultant of the general and of the local conditions It is also probable that the largest variations will be due to the general variation over the whole area of supply The data furnished by Captain Lyons are, on the whole in full agreement with these inferences The most remarkable case of similarity of seasonal variation is exhibited by the data of the past fourteen years The following gives comparative data of the rainfall of India and of the Nile floods from 1892 to 1905 The former data are obtained from the Indian meteorological publications, and the latter from Captain Lyons's memoir —

Year	Ratio of mean actual to normal rainfall in India	Ratio of actual to normal Nile flood
1892	1 12	1 20
1893	1 21	0 99
1894	1 15	1 22
1895	0 95	1 15
1896	0 88	1 06
1897	0 99	0 89
1898	1 01	1 07
1899	0 73	0 63
1900	0 99	0 89
1901	0 90	0 87
1902	0 95	0 63
1903	1 05	0 89
1904	? below	0 75
1905	much below normal	0 65
Period 1892 4	1 16	1 14
,, 1895-8	0 94	1 05
,, 1899 1903 or 1905	0 93	0 78

It is a noteworthy fact that the Abyssinian rainfall, as indicated by the Nile floods, is subject to much larger range of variation than the rainfall of India, as might perhaps have been anticipated The data show that from 1892-4 the rainfall in India and in Abyssinia (assumed to be roughly proportional to the total Nile flood) was in considerable excess from 1892-4, about normal from 1895-7 and more or less in defect from 1898 to 1905 The parallelism would have been more exact if the rainfall of western India had been given instead of that for the whole of India The 1896 drought in India was due chiefly to the weakness of the Bay current, and not of the Arabian Sea current It may be noted that the data for the variations of the level of the Victoria Lake agree generally with those of the Abyssinian rainfall, as indicated by the Nile floods Thus according to Captain Lyons 1892-5 was a period of high level, 1896-1902 a period of falling level, and 1903 a year of rising level This remarkable parallelism strictly in accordance with the general simple inferences stated above, suggests two problems for the consideration of meteorologists These are, first, the causes of the large variations from year to year of the rain supply over the immense land area of India the Soudan and Abyssinia, and, secondly, the determination of any invariable antecedent conditions which may serve as indications and be utilised for forecasting these variations Captain Lyons in the last chapter of his memoir takes up both of these problems, but acknowledges that his investigations are only in the introductory stage It is however, interesting that his present conclusions on the whole agree with those of Indian meteorologists He shows, for example that pressure in the Egyptian region is below the normal in seasons of good Nile floods and *vice versâ* This is the usual relation between pressure and rainfall in India, and is also in accordance with theory Captain Lyons also points out that the monsoon variations of pressure are frequently, if not invariably, the continuation of similar conditions which have prevailed for some time previously This is also in accordance with Indian experience He also points out that they are probably in some cases related to the widely distributed variations of pressure studied by Sir Norman Lockyer and Dr Lockyer, and also to the long-period variations in India The latter are marked by or accompany prolonged abnormal variations or anomalies of the Indo-oceanic air movement He also considers that they are occasionally determined by variations in the position and intensity of north-east Atlantic anticyclones This is by no means improbable but until more is known

of the actions that determine the displacement of the more or less permanent anticyclones it is doubtful whether an occasional coincidence could be accepted as sufficient evidence to establish a relation. Some meteorologists, we believe, consider anticyclones to be comparatively inert masses, and others, on the contrary, as sources of action. They are remarkably persistent in position and character, and their variation of position from one period to another in south-western Europe is closely related to the abnormalities of weather. Where theoretical opinions differ so largely it is almost certain that it will require twenty-five to fifty years' data at the least to test the relation between the Abyssinian rainfall and the position of the anticyclone in south-western Europe or the adjacent Atlantic.

NEW PHYSICAL AND ENGINEERING DEPARTMENTS OF THE UNIVERSITY OF EDINBURGH.

The new buildings for the natural philosophy (Prof. MacGregor) and engineering (Prof. Hudson Beare) departments of the University of Edinburgh were opened on October 16 by Dr. Andrew Carnegie in the presence of a large and influential gathering. The proceedings took place in the large lecture theatre of the natural philosophy department, and were presided over by the Chancellor, the Right Hon. A. J. Balfour. Part of an address entitled "A Plea for Science Teaching" delivered by Dr. Carnegie before declaring the buildings open was printed in last week's Nature (vol. lxxiv., p. 648).

The Chancellor then moved a vote of thanks to the benefactors. He was glad to have the opportunity of mentioning the work of the friends and admirers of the late Prof. Tait who had instituted a fund to encourage research, which he hoped would make these walls illustrious to all time. No more fitting tribute to Prof. Tait's memory could possibly have been contrived. Though Prof. Tait worked in what he could hardly call a laboratory, ill-equipped and wholly inadequate to the work of modern research, yet he left a name which for all time would be associated with the great development of physical knowledge which marked the last fifty years of the recent century—a movement which he believed would be conducted with ever increasing acceleration through the earlier years of the present century. He was glad also to have an opportunity of saying to Lord Elgin that the work he had done as chairman of the Carnegie Trust was a work for which he had earned the gratitude of every man interested in the fate of the Scottish universities and in the maintenance of the position which Scotland had held for more than 150 years in the world of learning. Proceeding, the Chancellor referred to Dr. Carnegie, whose munificent beneficence to many great causes, and so far as they were concerned especially to the Scottish universities, was known, and was destined to leave a permanent mark and do permanent good in Scotland.

Sir William Turner, in seconding the motion, referred to the great kindness of Sir Donald Currie, who, he said, had taken a great weight off his mind when he told him he need not be under any difficulty in finding the money to hand over to the municipality for the site on November 11 two years ago. He also desired to thank Sir John Jackson for his generous gifts, and stated that before long he hoped they would be in a position to receive from him a very handsome addition to the Tait memorial fund.

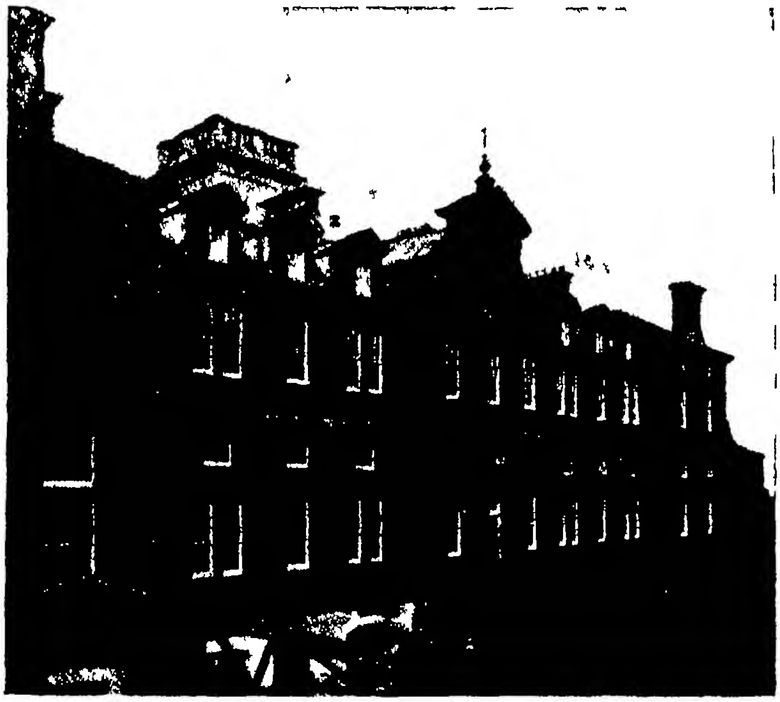

Fig. 1.—South front of new Natural Philosophy Buildings, University of Edinburgh.

Natural Philosophy Buildings.

The accompanying illustration (Fig. 1) shows the south front of this block of buildings. The building which has been transformed into a physical institute—the old surgical hospital of the infirmary—consisted of a main block 107 feet by 43 feet running nearly east and west, with wings at both ends 62 feet by 38 feet, and a block 71 feet by 51 feet running north towards the new engineering buildings, this north block including, at its junction with the main building, a tower 89 feet in height. The outer walls have been almost entirely utilised as they stood, with one important exception—on the southern side of the main building, by terracing the ground and piercing the lower part of the wall with large windows, the old dark basement rooms have been converted into lofty well-lighted laboratories. The interior has been largely reconstructed, and all the floors are now concrete, supported on cast and west steel girders.

The principal floor, entered directly from Drummond Street, contains the lecture theatre, apparatus rooms, library, professor's research rooms, &c. The lecture theatre, 45 feet long, 46 feet wide, and 32 feet in height, with seating accommodation for 250 students, is lit entirely from an opening in the roof, and is ventilated by an electric fan. The lecture table is 30 feet long, standing in an experimental area 15 feet wide; it is supplied with hot and cold water, high-pressure water, steam, gas, vacuum, air blast, oxygen, and a number of electric circuits, and a heliostat has been placed in a window of the apparatus room so as to send a beam of sunlight along it. Opening off the lecture theatre is a preparation room with the necessary work benches; this room contains also the main switchboard from which current will be distributed throughout the building from the town mains and from the accumulators. The apparatus room has a corridor entrance immediately opposite that of the preparation room; it is intended only for lecture apparatus. On the west side of the apparatus room provision has been made for a smaller lecture room, capable of accommodating about eighty students, and on the ground floor there is another small lecture room for the department of applied mathematics. The library and reading room is 37 feet by 29 feet, with a southern exposure, and opens off the entrance hall.

The upper floor and the ground floor are devoted to the laboratories and research rooms, the east wing of the upper floor is reserved for arts and science students, and the west wing for medical students The junior arts and science laboratory has accommodation for forty-five students, and is fitted with tables, benches, and wall apparatus for introductory experimental work, on one side is a long gallery for optical work The senior laboratory will accommodate forty students, and consists of three rooms for mechanical, thermal, and electrical work, two rooms for optical work, and two for sound Between these two sets of laboratories is a research room for the chief laboratory assistant, and adjoining them is a small workshop with benches lathe, glass-blowing table, &c

On the ground floor are the research rooms, at present only five are to be fitted up, the remainder will be equipped and brought into use as funds permit These rooms have firm concrete floors, have stone shelves built into the thick, solid walls, and are supplied with high- and low-pressure water, gas, electric currents, &c, and in certain of the rooms, by the use of copper and brass piping, and by other precautions, provision has been made for work with delicate electrical instruments On this floor are also the accumulator room, a large workshop and forge room, and a constant-temperature room

The tower, 89 feet in height, has been utilised for suspension of long wires, mercurial pressure-gauge and other purposes requiring considerable height, and, lastly, on the roof a floor space, 24 feet by 12 feet, has been arranged for open air experiments

Engineering Buildings

The accompanying illustration (Fig 2) shows the west end of the block of buildings for the engineering department

The building is Γ-shaped the head of the T facing west In the head of the T, on the ground floor, are provided large laboratories for the testing of materials (42 feet by 30 feet) and for hydraulics (51 feet by 30 feet) The first floor is devoted mainly to a laboratory for experimental work, which does not require heavy machinery (73 feet by 25 feet) On this floor are also a small lecture room, the departmental library, and the private rooms for the staff

The back block of the building is also divided into two floors—the lower forms the lecture theatre and the upper the drawing office The lecture theatre will seat about 120 students, and on the lecturer's table are all the needful appliances for experimental demonstrations, there being steam, gas, and electrical connections There are also the necessary appliances for darkening the room in order to allow of the free use of lantern demonstrations The drawing office is a fine room, about 45 feet square, lit entirely from the north and east, the roof being of the saw-tooth pattern, the floor space giving room for about sixty independent drawing tables Special rooms have also been set aside for blue-print work and photography

A workshop and heat laboratory (48 feet by 42 feet) has been provided for by roofing in and connecting to the main building a piece of ground lying in the north-east angle between the front and back blocks The workshop and laboratory contains examples of all the ordinary machine-tools gas-engines, steam-engines, and other plant for experimental research in connection with thermo-dynamics

The building is heated by hot water and by steam, an independent boiler house has been constructed for this purpose, with two large boilers

A considerable amount of additional apparatus has been installed in these new buildings The testing laboratory now contains a 100-ton Buckton machine, with the necessary electric motor, pump, and accumulator, a 60,000-lb Riehle machine, an Amsler 100-ton machine, specially designed for compression and bending work, and a complete installation for the testing of cements, mortars, &c

In connection with the hydraulic laboratory, a water tower has been constructed at the south-east corner of the building, at the top of this tower is a large cast-iron tank holding about 10 000 gallons, and giving a head of 65 feet above the floor-level of the laboratory The floor of the laboratory is on two different levels, on the upper level are placed the various turbines, water wheels and other hydraulic machines on which experimental investigations will be carried out The water discharged from these machines passes into one or other of three rectangular channels formed in the floor and the quantity is measured by allowing the water to pass over weirs The water then flows into one or other of two large rectangular tanks, each 11 feet square by 5 feet deep, sunk below the lower floor-level of the laboratory, where it is measured again by floats, with rods moving in front of carefully graduated vertical scales From these lower measuring tanks the water is lifted by an electrically driven 20 h p centrifugal pump back to the storage tank in the water tower The hydraulic equipment includes a Venturi meter and other forms of meters and a considerable amount of other apparatus for experimental work

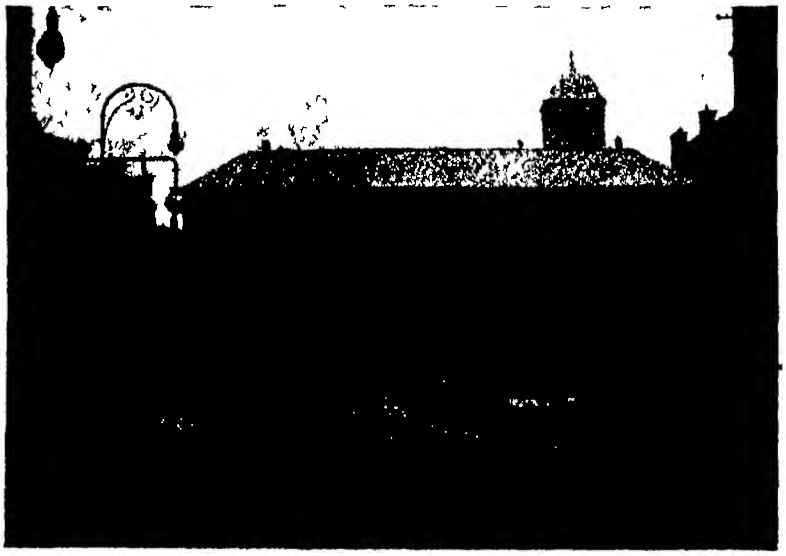

FIG 2 —Entrance and West Front of new Engineering Department University of Edinburgh

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD —The geographical scholarship for 1906 has been awarded to Mr N de Lancey Davis, Jesus College

Mr J A Brown, New College, has been appointed demonstrator in the laboratory of the Wykeham professor of physics

The following elections have been made at Jesus College —to scholarships in natural science, G I Wishart Wilson's Grammar School, London, S E, and H F Jones, County School, Towyn, to exhibitions in natural science R Atkin Nottingham High School, and A D Phoenix, Grove Park School, Wrexham

CAMBRIDGE —The following recommendations contained in a report of the special board for mathematics on the mathematical tripos, received the sanction of the Senate at a congregation held on October 25 —(1) A student may be a candidate for part 1 of the mathematical tripos

at a date not earlier than his second term and not later than his seventh term (2) A student who fails to obtain honours in part i of the mathematical tripos may be a candidate on a second occasion, provided he then be otherwise qualified (3) The examination for part i shall comprise the subjects in the schedule annexed to the report (4) The list of successful candidates in part i shall be arranged in three classes, the names in each class to be arranged alphabetically (5) The examination for part ii shall comprise the subjects in the Schedules A and B annexed to the report, together with certain questions partly on the subjects of the schedule for part i (6) The list of successful candidates in part ii shall be arranged in the three classes of wranglers, senior optimes, and junior optimes, the names in each class to be arranged alphabetically (7) In the examination for part ii the class in which a candidate is placed shall be in general determined by his performance in the papers on the subjects of Schedule A, a mark of distinction and a mark of proficiency being awarded to those candidates who acquit themselves with sufficient credit in the subjects of Schedule B

The Senate will be asked on Saturday, November 3, to assign a site in Free School Lane for the proposed extension of the Cavendish Laboratory, and to appoint a syndicate to consider the assignment of a site for the extension of the chemical laboratory Lord Rayleigh's munificent gift of 5000*l* out of the Nobel prize will go toward the cost of the new building for physics It will be remembered that the balance of the prize was given by Lord Rayleigh to the University library fund The extension of the chemical laboratory is called for because Gonville and Caius College are proposing to close their chemical laboratory at the end of the academic year

THE Cairo correspondent of the *Times* states that considerable interest has been aroused there by a proposal to found a national university, modelled on European lines, and independent both of the Ministry of Public Instruction and of the mediæval foundation of Al Azhar A committee, which includes the leaders of the progressive Mohammedan school of thought, has been formed to draft a programme of courses and to raise the sum of at least £E500,000 which will be required to make the university a reality In an appeal for public support, Kassim Bey and the other promoters of the scheme outline its features The courses of the proposed foundation are to be literary and scientific, open to all without distinction of nationality or creed Diplomas will be granted to students fulfilling conditions of attendance and passing the requisite examinations and no attempt will be made at the outset to encroach upon the primary, secondary, and technical instruction imparted by the various Government schools

LORD ROSEBERY, as Chancellor of the University of London, on October 26 performed the ceremony of opening the library of the University After expressing the gratitude of the University to the Goldsmiths' Company, which spent 15,000*l* in securing and supplementing Prof Foxwell's library, and explaining the growth of the University library as a whole, Lord Rosebery, among many other subjects of wide interest, spoke of the functions of a library He said there is no greater misconception of a library than to think that it can take the place of a university "No doubt a student must be fed by books, it is impossible for the student to proceed far without books, but I will urge a further consideration which I should think the experience of those of my age who are present will tend to confirm—that the mere habit of reading, and often of reading copiously, without any exercise or output for their knowledge, is injurious rather than beneficial to the mind It is apt to produce a condition of mental debility, if not of mental paralysis I hope that no students will ever believe that the library of this University is intended as more than a staff and an assistance, and not in any degree as the object of their training at this University"

MR HALDANE, as is appropriate to the president of the British Science Guild, avails himself of every opportunity to insist upon the value of knowledge and of scientific habits of thought in every sphere of human activity Distributing the prizes and certificates to the students of Birkbeck College on October 26, Mr Haldane said there is a danger which is inseparable from a college such as the Birkbeck College It is largely attended by those who have their bread to win, and whose main concern must be to win it and to win the leisure for learning. The temptation becomes very strong in such a case to look upon learning as being what the Germans call a *brotwissenschaft*—a scientific means of increasing the opportunities for earning a living That is a very cramping view, and one fatal to the higher learning But it is the higher learning that pays in these times—not the learning which is a means to an end, but the learning which is an end in itself Learning for learning's sake, that is the key to a career Not every person who has learning is necessarily successful in his career, but, other things being equal, the man who is penetrated with the spirit of the scholar has a far better chance in the race of life than the man who is not so penetrated What is true of individuals is true of nations A few years ago Japan was reckoned with those who were not civilised To-day, by singleness of purpose, by concentration upon science, by the dominant purpose of the nation to fashion its national character according to the highest ideas, Japan has leapt, at a bound almost, into the front rank Germany, too, has gone forward stride after stride on the basis of scientific re-organisation These are lessons that we do well to bear in mind

A NEW hall and buildings in connection with University College, Reading, were opened on October 27 by Mr Haldane, Secretary of State for War As has been noted in these columns, the new site was secured as a gift of Mr. Alfred Palmer, and the new buildings now opened bring the council an important step nearer the completion of its scheme for a fully equipped college The principal feature of the new buildings is the great hall in which the ceremony took place The science laboratories and art studios consist of seven separate buildings, and accommodation is provided for theoretical and practical work in biology, agriculture, physics, chemistry, and geography Mr Haldane, in the course of his speech declaring the new hall open, said —"It is impossible to set up technical education successfully on anything but the broadest basis of culture It is distressing to consider, not only how small a part the State has played in higher education in this country, but how misplaced its intervention at times has been The present Government proposes to spend an extra 1,000,000*l* a year on elementary instruction, and the late Ministry spent more than that sum additionally for the same purpose, but these payments arose out of controversies which had little to do with education The Government is doing something for the higher teaching, but its capacity is limited by what the people will allow. There is already a great awakening in this country with reference to higher instruction, but it is due to private donors far more than to the public generally The War Department wants several things dependent on education. It desires a great reserve of officers, and one thing that it is considering at this moment is how to get the universities and university colleges to assist it A great misfortune has come to the Army of late through the revelation, in relation to the South African War, of an altogether inadequate organisation and training, inadequate to cope with the great business of supply in time of war and the period following war Supply is a science by itself, which requires high training if the country is not to be victimised by contractors and everything is to be placed where it is needed The Army has organised its General Staff, which requires officers with the highest class of instruction for strategy, tactics, and general command This is one side of military education, but there is an administrative side also, and up to now no steps have been taken to give the highest education to administrative officers The Government has decided to train a school of administrative officers up to the high level that it is trying to attain for staff officers A certain number of officers will study at the London School of Economics, and it is hoped that they will form the nucleus of an administrative staff as capable as the general staff whether of our Army or any other

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, October 18 —Sir W Ramsay, K C B, F.R.S., in the chair —The Longstaff medal was presented to Prof. W Noël Hartley, F R S, of Dublin, for his researches in spectrochemistry —The description and spectrographic analysis of a meteorite stone W N **Hartley** This stony meteorite was seen to fall in the Kangra Valley, Northern Punjaub, in 1897 The principal constituents of the metallic portion are iron, nickel, cobalt, and chromium, with small quantities of copper, lead, silver, and gallium Manganese, calcium, potassium, and sodium are only present in minute proportions —Malacone, a silicate of zirconium containing argon and helium S **Kitchin** and W G **Winterson.** This mineral, found at Hitteroe and Arendal, Norway, is radio-active, and gives off a mixture of helium and argon when heated The analysis, discounting ferric oxide, uranium oxide, &c, points to the ratio $3ZrO_2 \cdot 2SiO_2$ between the zirconia and the silica —The relationship of colour and fluorescence to constitution, part i, the condensation products of mellitic and pyromellitic acid with resorcinol O **Silberrad** One of the chief interests of this work lies in its bearing on the quinone theory of the structure of the phthaleins Many of the compounds described do not admit of formulation on the quinone type, but are nevertheless intense colouring matters, and strongly fluorescent —Separation of αα- and ββ-dimethyladipic acids A W **Crossley** and Miss N **Renouf** —Action of alcoholic potassium hydroxide on 3-bromo-1 1-dimethylhexahydrobenzene A W **Crossley** and Miss N **Renouf** —The conversion of morphine and codeine into optical isomerides, preliminary communication F H **Lees** and F **Tutin.** The facts obtained permit of the following conclusions respecting the constitution of morphine —(1) the isomeric codeines are the result of the racemisation of two asymmetric carbon atoms in a molecule which must necessarily contain a third asymmetric system, (2) the carbon atoms which undergo racemisation are most probably those in the reduced phenanthrene nucleus to which the alcoholic hydroxyl group and the nitrogen atom are respectively attached, (3) The possible isomeric codeines must be represented by the configurations $++-$, $+--$, $-+-$, $---$ —The aminodicarboxylic acid derived from pinene W A **Tilden** and D F **Blyther** Details are given for the preparation of the acid and its hydrochloride, nitrate, acid oxalate, copper salt, ethyl ester and its hydrochloride, and the acetyl derivative —The preparation and properties of dihydropinylamine (pinocamphylamine) W A **Tilden** and F G **Shepheard** Dihydropinylamine is the chief product of the reduction of nitrosopinene by means of boiling amyl alcohol and sodium The hydrochloride, platinichloride picrate, nitrate, oxalate, also the acetyl and benzoyl derivatives and the carbamide, have been prepared and analysed —Determination of nitrates F S **Sinnatt.** It is shown that Knecht and Hibbert's method for the estimation of picric acid (*Ber*, 1903, xxxvi, 1549) may be applied to the estimation of nitrates —The nature of ammoniacal copper solutions H M **Dawson.** The experimental data obtained indicate the existence in solution of a dissociating complex compound containing four molecules of ammonia per atom of copper —The colouring matters of the stilbene group, part iii A G **Green** and P F **Crosland.** It is shown that all the dyestuffs of the stilbene series are true azo-compounds Their chromophor being an azo-group, their dyeing properties are now satisfactorily explained They differ however, from most other azo-dyestuffs in the entire absence of auxochrome groups —Interaction of succinic acid and potassium dichromate Note on a black modification of chromium sesquioxide F A **Werner.** When a mixture of finely powdered potassium dichromate (1 mol) and succinic acid (6 mols) is heated, a compound having the composition $Cr_4(C_4H_4O_4)_5\,7H_2O$ is formed which has not the properties of a chromo-organic acid The chromium hydroxide produced from it by decomposition with sodium hydroxide leaves a jet-black modification of the sesquioxide after ignition —Derivatives of polyvalent iodine The action of chlorine on organic iodo-derivatives, including the sulphonium and tetrasubstituted ammonium iodides F A **Werner** —The so-called "benzidine chromate" and allied substances J **Moir** This substance, which resembles cœrulignone, results on mixing solutions of benzidine and chromium trioxide It is the chromate, not of benzidine, but of a complex oxidation product of the latter —New derivatives of diphenol (4 4′-dihydroxydiphenol) J **Moir.** By the sulphonation of diphenol the author has prepared the 3 3′-disulphonic acid, the 3 5 3′ trisulphonic acid, and the 3 5 3′ 5′-tetrasulphonic acid —The interaction of the alkyl sulphates with the nitrites of the alkali metals and metals of the alkaline earths P C **Rây** and P **Neogi.** By the interaction of the sodium, potassium, barium, and calcium salts of ethyl sulphuric acid and the nitrites of the alkali metals and metals of the alkaline earths, both ethyl nitrite and nitroethane were formed —The electrolytic preparation of dialkyldisulphides Preliminary note T S **Price** and D F **Twiss.** By the electrolysis of a concentrated aqueous solution of ethyl sodium thiosulphate commonly known as Bunte's salt, diethyldisulphide is formed at the anode Similar results were obtained by electrolysing solutions of benzyl sodium thiosulphate, dibenzyldisulphide being produced —The direct union of carbon and hydrogen at high temperatures J N **Pring** and R S **Hutton.**—The action of nitrogen sulphide on certain metallic chlorides O C M **Davis** When nitrogen sulphide dissolved in dry chloroform is added to the tetrachlorides of tin and titanium, the pentachlorides of antimony and molybdenum, and also tungsten hexachloride dissolved in the same solvent, interaction readily takes place The compounds formed are represented by the formulæ $SnCl_4,2N_4S_4$, $SbCl_5,N_4S_4$, $MoCl_5,N_4S_4$, $WoCl_4\,N_4S_4$, and Ti_2Cl_8,N_4S_4 —The determination of halogen J **Moir**

PARIS

Academy of Sciences, October 22 —M H Poincaré in the chair —The work stored up in the trochoidal wave Émile **Bertin** —Distillation and desiccation in a vacuum with the aid of low temperatures MM **d'Arsonval** and **Bordas** The vapours given off pass into a condensation tube cooled either with liquid air or a mixture of solid carbon dioxide and acetone, according to the vacuum required After a preliminary exhaustion with a water-pump, the exhaustion is completed by a tube filled with charcoal immersed in liquid air or acetone and carbon acid snow, a Crookes's tube being used as a manometer The vacuum is maintained by the charcoal tube in spite of any slight leakages through the connections A diagram of the apparatus is given, together with full details for its use The following advantages are claimed for the method —the evaporated liquid can be weighed directly the evaporation taking place at the ordinary temperature and in the absence of air the dried substance is obtained without alteration, and the time required for the whole operation is much reduced Thus to obtain the dry residue from wine which required three days when evaporated in a vacuum by the ordinary method, three hours are sufficient – Contribution to the study of the calorific emission of the sun G **Millochau** and C **Féry** Details are given of the calibration of the apparatus described in a previous paper Basing the constant of the instrument on the calibration with an electric furnace, the temperature of which was taken as 1673° absolute, and correcting for atmospheric absorption, the temperature of the sun as given by observations at the summit of Mt Blanc is 5620° C —Researches on atmospheric lines Milan **Štefánik** By the application of the method of coloured screens the author has been able to study the telluric lines in the infra red A description is given of the instruments employed, observations being made at the Observatory of Meudon, Chamonix Grands-Mulets, and the summit of Mt Blanc —Isothermal surfaces of the first class L **Raffy** —Isothermal surfaces R **Rothe** —The conditions of complete integrability of certain differential systems M **Riquier** —The liquefaction of air by expansion with external work Georges **Claude** —A safety apparatus for providing against accidental sparks in the effects of wire less telegraphy Édouard **Branly** —The aurora borealis A reply to M Stormer P **Villard** —The existence of chloride of bromine Paul **Lebeau** The author has repeated the experiments of earlier workers under varying

conditions on the so-called chloride of bromine, and comes to the conclusion that no such compound really exists The crystals which can be obtained by cooling sufficiently a solution of bromine in liquefied chlorine have a composition depending on the temperature at which they are formed and are mixed crystals of the two halogens — Protoxide of cæsium E **Rengade**. It is possible to prepare the oxide of cæsium Cs_2O in a pure and well-crystallised condition by admitting a limited quantity of oxygen to a weighed amount of the metal When about two thirds the amount of oxygen necessary to form the Cs_2O has been admitted, the excess of the metal is slowly distilled off in a vacuum at 200° C The oxide remains in the form of orange-red crystals, reacting violently with water, and decomposing at about 500° C in contact with silver, and in the cold in the presence of liquefied ammonia the latter giving a mixture of the amide and hydrate of cæsium —*The pure alloys of tungsten and manganese, and* the preparation of tungsten G **Arrivaut**. In the reduction by aluminium a suitably high temperature of reaction is obtained by using Mn_3O_4, WO_3, MnO_2, and WO_2 in varying proportions Manganese-tungsten alloys can be prepared containing from 12 per cent to 60 per cent of tungsten By preparing an ingot containing 45 per cent of tungsten and submitting this to the action of hydrochloric acid, the residue was nearly pure tungsten 99 5 per cent — The products of condensation of acetylenic esters with amines Ch **Moureu** and I **Lazennec** The products of the condensation of the acetylenic esters $R—C \equiv C—CO_2R'$ with amines are non-basic bodies, easily hydrolysed by acids Hydrolysis regenerates the amine with formation of the ketonic ester $R—CO—CH_2—CO_2R'$ The reaction furnishes a new method of passing from the acetylenic esters to the β-ketonic esters —The atomic weight of dysprosium G **Urbain** and M **Demenitroux** A set of determinations carried out on the products of different fractions gave 162 54 (O = 16) as a mean of twelve very concordant results —The presence of formol in certain foods G **Perrier** By applying the very sensitive reaction proposed by Voisenet for the detection of minimal proportions of formol, the author has proved the presence of this substance in various articles of food the formaldehyde arising from the mode of preparation and not having been specially added In view of these results the author discusses the advisability of altering the existing law which absolutely prohibits the presence of formaldehyde in food substituting a maximum limit The azo colouring matters heat of combustion and constitutional formulæ P **Lemoult**.—The liquid crystals of cholesteryl propionate Fred **Wallerant**.—The action of copper salts on the germination of Penicillium M **Le Renard** — The variations of assimilation with light and temperature W **Lubimenko** — The swimming mechanism of *P maximus* Fred **Vles**.—*Mesoglicola Delagei*, a parasite of *Corynactis viridis* A **Quidor** —The units of the hæmatozoa of paludism M **Thiroux** The Dolichopodidæ of amber from the Baltic Fernand **Meunier**

THURSDAY, NOVEMBER 8, 1906

SCIENCE AND FOLLY

The Seven Follies of Science a Popular Account of the most famous Scientific Impossibilities and the Attempts which have been Made to Solve Them By John Phin Pp viii + 178 (London Archibald Constable and Co, Ltd, 1906) Price 5s net

THESE "Follies" are the squaring of the circle, the duplication of the cube, the trisection of an angle, perpetual motion the transmutation of metals the fixation of mercury, and the elixir of life, we miss from this list the flattening of the earth The author is an American, he writes for ordinary readers, and makes his subject interesting, he seems to make no mistakes He dwells at much greater length upon the first and fourth of the follies than the rest In addition to these seven classical ones he gives an account of four others perpetual lamps, the alkahest or universal solvent, palingenesy (the revival of a plant or animal from its ashes), and the powder of sympathy He adds a division on the fourth dimension of space and some paradoxes, micrographv illusions of the senses, and two tricks The book finishes with an account of some arithmetical problems and the fulcrum of Archimedes which are probably "curious" to the ordinary reader

Readers of NATURE and not merely ordinary readers, may spend a pleasant hour or two in looking through this book reflecting on the follies, not of scientific persons, but of those persons supposed to be cultured who are ignorant of physical science in an age when applications of the principles of physical science are transforming the world Our greatest legislators and writers and divines are no better guarded mentally from tricksters than their ancestors We know that a new Mahomet might have just as much success with cultured and uncultured persons in the twentieth as in the seventh century, but it is startling to find that a new Caghostro might probably be even more successful in the twentieth than in the eighteenth century A scientific man does not deny the possibility of almost any miracle, he only says that it is extremely improbable He admits that man is probably limited in his senses and faculties, and that all his physical laws are mere analogies, that real comprehension of the universe is altogether out of the question These admissions have become known now to unscientific persons, and no Swedenborgian was more ready to take the cock-and-bull statements of his master on trust than 99 per cent of newspaper readers and writers at the present time are willing to accept absurd stories as true A cultured person says that of course a perpetual motion is impossible, but he invests his money in a company which promotes something which is really meant to create energy He scorns the Middle Age idea that a sympathetic powder applied to a dagger will cure a distant wounded person but although he has been to a public school he is a profound believer in Christian science

Few men probably receive more communications from earth flatteners and circle squarers and arc trisectors than the present writer When he receives one he does not feel pleased, and yet it ought to be pleasant to think that there are so many men in the world who refuse to accept dogma A *crank* is defined as a man who cannot be turned These men are all cranks, at all events we have never succeeded in convincing one of them that he was wrong The usually accepted axioms, definitions, and technical terms are not for them When they use a term sometimes evidently in two different senses in the same syllogism it is impossible to find exactly what they mean by it If Mr Phin had had his reviewer's experience, he would have greatly added to the size of his book by referring to many parts of physics where men are just as unwilling now to accept authority as the men of whom he writes, and he would have pointed out that our real difficulty is with the men who are partly right men who think they have a new idea and try to explain it in unscientific language, and as they do so denounce the orthodox beliefs which they have been unable to understand

From many follies the common people have been saved for ever by the engineers the men who apply science In this twentieth century it is difficult to believe in sympathetic wax images and powders and the other things cherished by our ancestors who executed witches, because miraculous railway trains and telegraphs and telephones and thousands of things to be seen in every shop on every street on every road are known to be explainable in reasonable ways To believe now in the evil eye or devil possession ghosts haunted houses or the powers of the esoteric Buddhist it is necessary to have a very special kind of mental power and of education and environment It may be that only one in every 100,000 of the inhabitants of these islands is capable of snatching the fearful joy which accompanies such beliefs

As already said, we think that the author of this book makes no mistakes, but if he had known more he might have made the book a much larger one with advantage, and we cannot help thinking that he is not well read in the delightful memoirs of the sixteenth century, when witchcraft had a really good time Then as to a fourth or twentieth dimension in space, he gives practically no information to the expectant reader in this division of his work, yet there is probably no subject on which the cultured reader of the present day desires instruction more (perhaps excepting *radium*) A man may get some knowledge of Greek or Japanese literature without knowing the Greek or Japanese languages, and so the cultivated person hopes to get scientific ideas without knowing the language of science The author hardly tries to hide his own ignorance of this part of his subject and here, as everywhere else, he gives only what he himself feels sure that he understands He writes for the man in the street and we can give no higher praise than to say that the man in the street will understand him

J P

in the cotton gin has been made since it was introduced"—more than 100 years ago—and an authority is quoted as saying that "the saw gin actually wastes or destroys over 6 per cent. of all the cotton raised in the Southern States, meaning the destruction each year of nearly 40,000,000 dollars worth of property belonging to the farmers of the South." By other quoted authorities it is stated that "the saw gin destroys over 40 per cent. of the initial strength of the cotton fibre." It is also pointed out that, besides this waste, cotton can only be pressed to 14 lb. per cubic foot at the ginneries.

"A fortune," say the authors, "awaits the man who will invent a compress requiring small horse-power so that the bales, with one handling at the gin, may be compressed tightly enough for export purposes, just as a fortune awaits the man who will invent a roller gin for upland cotton by which the present waste and the barbarous laceration of the fibre may be obviated."

Such a statement is strong testimony of the authors' lack of knowledge of cotton affairs. Do they not know that there is a press in their own country which can be affixed to a gin and turn out a bale compressed to 35 lb. per cubic foot, and that it only takes 5 h.p. to drive it? Do they not know that in England gins are built which neither cut the cotton nor weaken the fibre, whether used on the long staple of Egypt or the short staple of India? Do they not know that American trusts are trying to defeat one of these longed for improvements, and American tariffs prohibit the other?

The remarks about baling are specially interesting as coming *from friends of the farmer*. After observing that "like the gin, the baling press has been materially improved in rapidity and in efficiency" (they told us on a previous page that no noteworthy improvement to the gin had been made since it was introduced, and that the old horse-driven gin did better work than the modern steam-power gin), they remark that "as a rule the American bale is not prepared with such care as its importance demands"; that the covering is torn, allowing the lint to drop out; that on bringing it back from the gin the farmer puts it under the apple tree or in the barn lot, or in some open, exposed place, "where rain and dust attack and damage it, and even pigs are allowed access to it on which to clean their muddy backs."

After making such a charge against the business capacities of the cotton farmer, is it not stretching a point to ask us to believe that these people who so mismanage their own business can by combination regulate the buying and selling of cotton on better or more economical lines than on the old law of supply and demand?

"Cotton" is very well printed, its illustrations are excellent, but from its numerous examples of bad English, the rhetorical extravagances indulged in by the authors, and the narrow views they take of political economy as affecting nation and nation, we are afraid their chances of being accepted as authoritative contributors to human knowledge are greatly jeopardised.

BOTANICAL DICTIONARIES.

(1) *Illustriertes Handwörterbuch der Botanik.* By Several Authors, and with the collaboration of Dr. O. Porsch and C. K. Schneider. Pp. vii+690, with 341 figures. (Leipzig: Engelmann, 1905.) Price 16s. net.

(2) *Dizionario di Botanica Generale.* By Dr. Guglielmo Bilancioni. Manuali Hoepli. Pp. xx+926. (Milan: U. Hoepli, 1906.) Price L10.

(1) IT would be an interesting question to discuss in its technical connections what are the differences between a glossary, a dictionary, and an encyclopædia of botany, but space will not allow of that, and we may pass on to say that this heavy book, typically German and written by Germans for Germans, stands in sharp contrast, with its unequal paragraphs—for instance, more than two pages and a half are devoted to *Drusen*, none to *Zelle*, and only half a page to *Zell-kern*—to the light and neat English "Glossary of Botanic Terms" of our own countryman Mr. Daydon Jackson.

The authors admit that the book has been designed to exclude antiquated terms on the one hand, and the most modern terms of the English-American and French literature on the other; they anticipate the question "How are we to draw the line?" and have decided that all purely descriptive expressions shall be excluded. But what are we to say to a "Handwörterbuch" from which all terms belonging to biochemistry and micro-technique, &c., except a few arbitrarily selected general terms, such as "swelling," "fermentation," "catalysis," "turgescence," &c., are excluded?

That the book contains an enormous amount of carefully collected information is sufficiently guaranteed by the names of the collaborators, but it is not a dictionary in the true sense of the word, and it is a very incomplete encyclopædia. The illustrations are good, but the majority of them are old and well-worn friends transferred bodily from the text-books of Sachs, De Bary, Frank, and others. To the ordinary student in this country the book can have little value; to the expert and experienced investigator it will have sufficient attractions for him to place it on his shelves. Of course the position it may be accorded in Germany, for the German student, is another matter with which we have nothing to do.

(2) Here we have a neatly-got-up book far more in accordance with the idea of a dictionary, though even here some of the paragraphs are too long and drawn out in the form of encyclopædic articles.

The preface begins "Vi fu chi affermò che il più interressante di tutti i libri è un dizionario." This may be so, in spite of the story, apparently unknown to the author, of the Scotchman who was found steadily perusing a dictionary from cover to cover with the sole complaint that the matter of the story seemed somewhat disconnected. A useful feature of the book is an appendix of biographical sketches of botanists, living and dead; this is necessarily very short and incomplete. There are no illustrations.

Taking these two works together, they may be recommended to the expert botanist, as said, as books of reference in cases where he wishes rapidly to extend his definition of special terms.

OUR BOOK SHELF

First Steps in the Calculus. By A. F. van der Heyden. Pp. vi+216. (London: Edward Arnold, 1906.) Price 3s.

THE modest claim expressed by the author in his preface, in the hope "that a step in the right direction has been taken towards producing a text-book suitable for an ordinary class in a Secondary Day School," is a claim which it would be impossible to deny. Experience has shown that geometrical illustrations, such as those on pp. 32–34, 45, and 96, are actually of great help to beginners, and we quite agree with the author that complicated theorems, such as Taylor's expansion (when applied to any but rational integral functions), should not be taken too early. The introduction (p. 93) of Lodge's treatment of the connection between integration and summation would be good if the step where the assumption is made were clearly pointed out. But there are many points which the author might have considered more fully before issuing the book. While the sine and cosine are properly differentiated it is surprising to find such a clumsy method employed for the tangent. In order to differentiate a power the beginner is required to swallow the usual series of terms which vanish in the limit instead of treating the power as a product.

In one or two places, in putting the chord of a curve equal to the corresponding arc, a line of explanation or even a reference number, would have made things much clearer. The introduction of e as early as chapter vi. is no doubt in accordance with traditions, but it is a pity to defer the study of the calculus until the text-books in algebra referred to for a discussion of exponential series have been read. Rational integral functions with applications to geometry and physics, afford plenty of material for the beginner. Lastly, the questions in examples ix. are very important indeed, but they give difficulty to many students who can hardly be described as beginners. The general conclusion is that the book would be more correctly described by a title which did not suggest something so *very* elementary. It is well suited for the class-room.

A Manual of Hydraulics. By R. Busquet. Translated by A. H. Peake. Pp. viii+312. (London: Edward Arnold, 1906.) Price 7s. 6d. net.

THIS book is a translation of a French treatise on hydraulics by Prof. Busquet, of the École industrielle de Lyon. It claims to be a text-book of applied hydraulics in which complete technical theories and all useful calculations for the erection of hydraulic plant are presented. The translator appears to have done his work well and to have given the meaning of the author in English terms and phrases. While the same arithmetical methods used in the original have been adhered to, the dimensions have been changed into ordinary British units, and the constants given in the formulæ have been modified to suit the change. The first three chapters deal with the elementary principles of the flow of water in open channels and pipes, and the last chapter with the flow over weirs. These subjects are dealt with in a simple and practical way. They do not, however, contain any information that is not to be found in English text-books on the same subject.

The fourth chapter, which occupies about half the book, is devoted to the theory and description of hydraulic motors and engines used to transform the energy contained in a head of water into mechanical work. The use of waterfalls hitherto has been limited, because the application of the energy could only be used locally, but since electricity has come into use for the transmission of power to great distances, water has assumed a new and increased value as an economical source for the production of power, and the construction of hydraulic installations is increasing at a rapid rate. The use of water-power and the machinery required to adapt it to commercial use have received very little attention from the authors of modern English and American treatises on hydraulics.

The writer does not know of any book that deals with this subject in so practical a way as the one under notice. The several kinds of water-wheels in use are described and illustrated, and their theoretical and useful value demonstrated. Turbines, which are now being largely used for the distribution of water-power, are freely dealt with, and the merits of the different forms of this machine discussed. The book is calculated to be of service both to students of practical hydraulics and to those engaged in designing and carrying out works for the utilisation of water-power.

Guide to the Principal Families of Flowering Plants. (After Engler's System.) By J. Adams. Pp. iv+40. (Dublin: Sealy, Bryers and Walker, 1906.) Price 1s. net.

A CONVENIENT summary for determining the orders of flowering plants is a much required desideratum. The difficulties in compiling such a summary are very great, not the least being due to the impossibility of defining the limits in certain cases between allied orders. Mr. Adams has not attempted such details, preferring to leave out a large number of orders and to sacrifice difficult distinctions to brevity and general utility. With regard to the statement that the book is after Engler's system, this applies only to the names of the orders, the method of separation is purely artificial. Thus in the Archichlamydeæ parasites and insectivorous plants are first eliminated, then consideration of the vegetative organs provides the next stages in differentiation. So far as practical tests have been applied with a few orders, the tables have given quite satisfactory results.

The Extra Pharmacopœia of Martindale and Westcott. Revised by Dr. W. Harrison Martindale and W. Wynn Westcott. Twelfth edition. Pp. xxx+1045. (London: H. K. Lewis, 1906.) Price 10s. net.

THIS most useful volume has now reached its twelfth edition, and extends to more than a thousand pages. The pages are small ones, but packed with information, and the paper is thin, so the volume still remains one of handy size. The book is more than its name indicates; it not only includes remedial agents which have been introduced up till now into medical practice, but contains a great deal of information regarding recent research in disease. For instance, we find an excellent summary of the present state of the cancer question, the newest methods of bacteriological investigation, and a concise statement of modern views on toxins and antitoxins, serum therapy, opsonins, and the like. No busy practitioner can afford to do without such a convenient and trustworthy *vade mecum*.

The Extirpation of the Tsetse-fly: a Correction and a Suggestion.

IN my letter published in NATURE of October 25 on the breeding haunts of the tsetse-fly discovered by Dr. Bagshawe, I stated that there were no banana plantations on the deserted island of Kimmi, on the Victoria Nyanza, and suggested that the flies there must have some other breeding-places than the plantations. I am informed, however, by my friend and colleague Lieut. A. C. H. Gray, R.A.M.C., who has just started for Uganda, that he and the late Lieut. F. M. G. Tulloch, when collecting flies on Kimmi, came across deserted banana plantations, overgrown by the forest and bearing ripe bananas (a sure sign that no natives visit them or know of them). I must correct, therefore, my former statement.

If the banana plantations should prove to be the sole or principal breeding-place of the tsetse-fly, the question at once arises, what means could be taken to exterminate the fly or check its increase? To destroy the plantations would be impossible, as I have said, because the banana is the staple food of the country. I venture to suggest that an efficient means of keeping down the tsetse-fly would be to encourage or constrain the natives to keep fowls in their plantations in places where the fly is abundant. These birds would scratch up and discover the pupæ much quicker than a man could, and would probably devour them greedily when found. In forest districts it might be seriously considered whether it would not be advisable to introduce the Indian jungle-fowl for the same purpose. It is, of course, always a risky thing to introduce exotic wild species into a country, but the jungle-fowl, being a valuable game-bird, could hardly be a serious nuisance, however much it multiplied.

I would suggest, further, that a most suitable place in which to try experiments on the extirpation of the fly would be the island of Kimmi already mentioned. Within easy reach of Entebbe, uninhabited, covered with forest or jungle, and swarming with tsetse-flies, it is a locality in which it would be very easy to introduce the jungle-fowl and to watch the effects. As there are no monkeys, so far as I am aware, on the island, the fowl would probably be able to flourish and multiply unchecked. Such an experiment, even if it failed to produce the desired effect, could do no harm, and if it succeeded would be of very great importance. E. A. MINCHIN.

The Efficiency of the Present Process of Natural Indigo Manufacture.

IN NATURE of September 20 (vol. lxxiv., p. 526) I find mention of a paper read before Section B at the recent meeting of the British Association by Mr. W. Popplewell Bloxam on a new method of determining indigotin. It is stated that "the author concludes that the present process of manufacture is a wasteful one, the highest efficiency attained not reaching 50 per cent., whilst on the average only 25 per cent. of the indigotin in the leaves is extracted."

In justice to the indigo-planting community in India I think this statement should not go unchallenged. The grounds on which Mr. Bloxam draws his conclusion are not given in the brief *résumé* of his paper in NATURE, and I am therefore obliged to seek an explanation in his communication to the Journal of the Society of Chemical Industry of August 15 on the same subject, in which a similar statement of the low efficiency of the indigo-manufacturing process is made. In this paper Mr. Bloxam gives the analysis obtained by his new method of the indigo turned out each day during the manufacturing season at a certain factory in Bihar. From the figure so obtained and the total daily outturn of finished indigo recorded in the factory "mahai" book, he calculates the amount of indigotin produced day by day, and from the proportion existing between the amount so calculated and the amount theoretically obtainable, deduced from the weight of green plant placed in the vat and *the assumption that this plant contains 0.6 per cent. of indigotin*, he arrives at his estimate of the efficiency of the manufacturing process.

Now it is clear that in this method of calculation error may occur in the following particulars:—

(1) The analysis of the finished indigo.
(2) The weighment of the daily outturn of finished product.
(3) The weighment of the green plant.
(4) The assumed content of indigotin in the green plant.

The first point is one for discussion elsewhere. It is sufficient for my present purpose to point out that the average of Mr. Bloxam's results (60 per cent. indigotin) agrees substantially with the average quality usually accepted as typical of Bihar indigos, and that, therefore, his results probably do not differ very widely from the truth. The same cannot be said of the second point. Separate weighment is hardly ever made of the daily outturn of an indigo factory, and I know as a fact that this was not done in the case on which Mr. Bloxam bases his figures. A rough estimate of the outturn is arrived at by measurement of the cakes produced in a wet condition, and the result obtained generally falls short of the actual production by 10 per cent. to 30 per cent. Mr. Bloxam must therefore have obtained his figures from cake measurement—at best a very inaccurate proceeding.

Similar inaccuracies occur in the weighment of the green plant in the ordinary factory routine, but the culminating error on which Mr. Bloxam's figures are based occurs in his assumption of 0.6 per cent. as the amount of indigotin occurring in the green plant. It has been my privilege to serve the indigo planters in Bihar in a scientific capacity for nearly five years. During this time I have carried out some hundreds of analyses of indigo plants of all varieties, ages, and sizes, and in only one or two cases has so high an indigotin content as Mr. Bloxam assumes is normal been recorded. These were in cases of the Java plant (*Ind. arrecta*, which contains an exceptional amount of indigotin, and was only being cultivated on a small scale during the season from which Mr. Bloxam's conclusions are drawn) under peculiar conditions of manuring. It would be more accurate to place the average indigotin content of the plant used during the season quoted by Mr. Bloxam at 0.3 per cent., so that his estimate of the efficiency of the manufacturing process should be doubled.

As a matter of fact, recent work, carried out with attention to the details I have enumerated, has shown that the process may with care, but with no modification other than is available to every planter, be rendered as efficient as 70 per cent. to 80 per cent., and that as it is carried out by the average planter it seldom falls below 60 per cent. C. BERGTHEIL.

The Research Station, Sirsiah, Mozufferpore, India, October 10.

The Leonid Meteors.

THOUGH the Leonid epoch of 1905 does not seem to have been marked by a great abundance of shooting stars, a magnificent aurora having unexpectedly taken the place on the evening of November 15 of the shower anticipated later on that night, yet it is probable that in the absence of moonlight and cloud the radiant in Leo would have been found to be more active than seemed to be the case. The phase of the moon renders the conditions for good observations more favourable in the present year, and it is probable that if the weather during the critical period turns out fine, Leonids will be observed in considerable numbers. In 1906 these meteors become due on the night of November 15. The anticipated display is connected by the nineteen-year period with the shower of November 14, 1868, and, like the latter, will be visible over both Europe and America. As calculated by the writer, the principal maxima take place on November 15 at 12h. 45m., 14h., 19h., and 21h. 40m., G.M.T. These maxima will therefore occur on the morning of November 16, the first two being visible here, while the remaining two, which repre-

sent by far the stronger portion of the shower, will fall to the lot of American observers

The calculated intensity of the shower is rather inferior to that of its prototype of 1868, besides, the first maxima fall early in the night, and may not, therefore, be seen at their best Nevertheless, the present epoch is a well-defined one, and should yield satisfactory returns to the vigilance of meteor observers.

Of the minor showers associated with the period, the most interesting occur on November 16 between 13h and 14h, and on November 17 from 13h to 18h

Dublin JOHN R HENRY

The Rusting of Iron

IN reference to the discussion on the rusting of iron in recent numbers of NATURE, I happen to have a curious specimen illustrating the accumulating of rust which may possibly be of some little scientific value It is a horse-shoe which was dug up some years ago by a child out of the sand on the site of the battle of Prestonpans, near Edinburgh It was given me by the child's father, who was with him at the time The shoe is now very irregular and lumpy The thickness of the naked iron can be made out at one spot, where it is partially denuded It is just three-eighths of an inch But with the mass of what I can only describe as rust, and I presume sand—some small pebbles are, too, imbedded in it—it is in one spot as thick as 2 inches, and in girth it there measures 6⅝ inches No part of it is wholly clear of rust, the smallest girth is 4 inches

The famous battle was fought on September 21, 1745, and the supposition is that the shoe if not the horse was lost there The supposition is probable enough If correct the rust would represent the accumulation in a century and a half I may add that I have some specimens of pig-iron which were turned out at foundries here fifty years ago, and have been in the open air ever since They have just a brown coat, but the coat is of no perceptible thickness

JOSEPH MEEHAN

Creevelea Drumkeeran, October 29

PROTOZOA AND STATOZOA[1]

THE late publication of the first volume of this well-known series has enabled the authors to incorporate some of the results of the more recent researches upon their several subjects Taken in conjunction with the earlier published volumes, the work seems to fulfil the purpose of providing an intelligible and adequate survey of the entire animal kingdom without giving undue prominence to particular groups

Prof Hartog's share in the work makes a well-timed appearance in the year which has witnessed something like a crisis in the history of protozoology His chapters are full of suggestive comparisons and analogies, and their value is increased by the addition of copious footnotes Some of the statements are not supported by references as, for example, where he speaks of the presence of a contractile vacuole in the zoospores of algæ and fungi without mentioning any specific instances of this condition (p 15)

The essential complexity of the simplest manifestations of living matter is made evident, and Prof Hartog does not harmonise the vitality of protoplasm with the vagaries of a drop of oil or of a bubble The segmentation of the oosperm of Metazoa and Metaphyta is compared with the sporulation of the Protista, both phenomena being characterised as brood-formations (p 31)

In the second chapter the author begins with an interesting disquisition on the old belief in spontaneous generation as an explanation of the origin of the organisms of putrefaction, pointing out how this was due in part to the supposed inconstancy of species in Protista, and that this in turn resulted from the want of knowledge of their life-histories, how this knowledge was supplied in the first place by the Rev W H Dallinger and Dr Charles Drysdale for Protozoa, and for the Protophyta by F Cohn and later by von Koch, who perfected the methods of culture devised by De Bary for the study of the fungi

In his remarks on reproduction by syngamy Prof Hartog distinguishes between exogamy and endogamy, the rhizopod Trichosphærium affording an example of the exogamous conjugation of biflagellate isogametes while the heliozoan Actinosphærium practises endogamy

Referring to the pelagic foraminifer Globigerina (p 61), the author says that after death the tests sink to the bottom of the sea to form the "Globerina ooze" (sic), "at depths where the carbonic acid under pressure is not adequate to dissolve the more solid calcareous matter" On the following page we read —"Some Foraminifera live on the sea bottom,

FIG 1—*Cerianthus membranaceus* in its tube Colour pink, with tentacles annulated pink and brown About 35 cm in length From The Cambridge Natural History, vol 1

even at the greatest depths and of course their shell is not composed of calcareous matter" There is nothing to indicate to the reader why this is more obvious than any of the other plain statements in the book

The first three chapters of Dr Hartog's treatise deal with the Sporozoa the Flagellata, the Ciliata and the Suctoria As an illustration of the rapid strides of recent years he notes that seven years ago no single species of Sporozoa was known in its complete life-cycle It would have been better to have used the general expression "body-cavity" instead of "cœlom" on p 105 Cœlom and hæmocœl are both body-cavities, just as clothes props and thoroughbreds are both horses!

The importance of investigations into the life-

[1] "The Cambridge Natural History" Vol 1 Protozoa by Prof Marcus Hartog, Porifera (Sponges), by Igerna B J Sollas, Cœlenterata and Ctenophora, by Prof S J Hickson, F R S Echinodermata by Prof E. W MacBride, F R S Pp xvii+671, illustrated (London Macmillan and Co., Ltd, 1906.) Price 17s net

histories and microchemical properties of the Protozoa which may be said to have achieved their present culmination in the life and death of Schaudinn, is worthily presented by Dr Hartog

Miss Sollas's three chapters commence with a brief historical introduction followed by a lucid description of two typical British sponges *Halichondria panicea* and *Ephydatia fluviatilis* The traces of a nervous system referred to on p 39 of this volume are not to be found here Chapter viii concludes with a key to British genera of sponges, comprising seventy-one names, and chapter ix deals with questions of reproduction, physiology, and the formation of flints

Turning now to Prof Hickson's valuable contribution, we note that he treats the Cœlenterata and the Ctenophora as separate phyla instead of regarding the former as divisible into two branches the Cnidaria, those which are armed with stinging threads, and the Ctenophora, those which are provided with swimming plates A more serious change which he has introduced is the resolution of the old order Hydrocorallina into two distinct orders, Milleporina and Stylasterina the former second the latter sixth, in the list of orders, separated in the text by the Gymnoblastea, the Calyptoblastea, and even the Graptolitoidea

With regard to the relations between the hydroid stock or hydrosome and the medusoid gonophore or medusome of the Hydrozoa, Prof Hickson gives expression to the perennial "vexed question" as to whether the hydrosome preceded the medusome or *vice versâ*, he does not assist the reader by adducing analogous instances The stock and sexual stolon of some annelid worms would seem to offer an almost exact analogy to the hydroid and medusoid phases of a hydrozoan, the medusome might even be regarded as an epitokous sexual phase, the stock being the parent form, indifferently whether it is fixed or free, the liberation of the medusæ (where this occurs) would correspond broadly with the swarming of the epitokes

The general treatment of the three classes Hydrozoa, Scyphozoa, and Anthozoa, leaves little to be desired within the limits prescribed by the nature of the work, and prominence is given to bionomical questions

Prof Hickson's last chapter is concerned with those wonderful creatures of the plankton, the Ctenophora In describing the planes of symmetry of the body, the author speaks of the tentacular or "transverse" plane and of the "sagittal" plane These animals show no antero-posterior differentiation, and only in one order, the Platyctenea, do they exhibit dorso-ventral differentiation, their symmetry is biradial, and it is undeniably inaccurate to saddle them with transverse and sagittal planes If a comparison with higher forms must be made, there are strong reasons for the belief that the tentacular plane of the Ctenophora should be likened to the sagittal plane of Bilateralia

In his account of the siphonophoran body (p 298) Prof Hickson evinces a general willingness to steer clear of wearisome polemical discussions, in this case the difficulty might have been surmounted by calling the various parts of the colony neither organs nor zooids, but organozooids

The volume concludes with six chapters on the Echinoderms from the pen of Prof MacBride In the classification of the Ophiuroidea the author has followed Prof Jeffrey Bell's system which seems to have achieved the distinction of permanency The tabulation of the families of Asteroidea is based upon Prof Perrier's system and gives a very different sequence from that based upon Mr Sladen's orders also in vogue at the present time In the chapter on the Echinoidea (sea urchins) there are interesting passages on the physiology of the pedicellariæ, the chapter on the Holothuroidea (sea cucumbers) contains a humorous though instructive comparison between the organisation of a Synaptid and that of a Sipunculid

The final chapter is devoted to questions of development and phylogeny It seems probable to Prof MacBride, and will doubtless appear so to his readers, "that Vertebrata and Echinodermata both arose from Protocœlomata" It remains to be added that the illustrations are excellent, and many of them original

The term "Statozoa," originally applied to certain Echinodermata, but not generally adopted in that connection, may be conveniently extended so as to include such animals as sponges, cœlenterates, and echinoderms, in which a fixed condition is either actually or phyletically predominant

THE INTERNATIONAL GEODETIC CONFERENCE AT BUDA PEST

THE International Geodetic Association held its triennial conference at Buda Pest from September 20 to 28, and I had the honour of serving as the delegate of our Government. By the kindness of the Hungarian Academy the meetings were held in their handsome building, and the arrangements for our reception, which had been made by M. Louis de Bodola, were in every way admirable. Before considering the scientific work of the conference I may mention that the Prime Minister, Dr. Wekerle, invited the members of the "Permanent Commission" to dinner, and that the Archduke Joseph afterwards received all the delegates at the palace. On subsequent days the Burgomeister of Buda Pest gave a dinner in our honour, as also did Count Albert Apponyi, Minister of Public Instruction.

The work of the conference was more interesting than that of any other at which I have been present, and the time was barely sufficient for the adequate discussion of many subjects of importance. In an article of this character it will clearly be impossible to do more than indicate in general terms the subjects which were considered.

The systematic observation of the variation of latitude, which is the special province of Dr. Albrecht, was naturally the subject of much discussion. The existence of a mysterious term in the expression for the position of the pole was discovered some years ago by Prof. Kimura. If this term, which is denoted by the letter z, has a real physical existence it would indicate that the equator oscillates backwards and forwards, moving parallel to itself. It appeared that observations conducted in the southern hemisphere would quickly determine the reality of the supposed motion. Accordingly, at the conference of Copenhagen in 1903 it was resolved that observations in the southern hemisphere should be instituted, and should be carried out for a period of at least two years. The southern observations of latitude are to be made at Bayswater, West Australia, where Dr. Hessen began his observations on June 6, 1906, and at Oncativo, in the Argentine Republic, where Prof. Carnera began work on May 5. These two stations are in S. latitude 31° 55′. We also heard from Mr. Innes that latitude observations will probably be commenced at Johannesburg (S. latitude 26° 12′) by the end of the present year. With regard to the observations in the northern hemisphere, it was resolved that they should be continued, at least until the year 1909, when the next conference will meet. The northern stations are Pulkova and Leyden, and in N. latitude 39° 8′ Mizusawa, Charjui, Carloforte, Gaithersburg, Cincinnati,[1] and Ukiah, together with Tokyo in latitude 35° 39′. Prof. Helmert gave an interesting account of the present condition of the whole investigation, and he directed attention to certain oscillations or systematic errors of which the physical meaning is as yet altogether obscure. Whatever their meaning may be, their magnitudes are excessively minute.

Another report of importance was one by Dr. Albrecht on the use of wireless telegraphy for the determination of differences of longitude. He concludes that this method may be relied upon to give as good results as those derived from telegraphy through wires.

Dr. Hecker had undertaken, at the expense of the association, a second long sea voyage for the purpose of determining the value of gravity at sea. His first voyage was from Portugal to Brazil, and the second was in the Indian Ocean and across the Pacific. He presented a short preliminary report in which he stated that the intensity of gravity for the deeper part of the Pacific Ocean is approximately normal and agrees closely with Helmert's formula of the year 1901. His experience in the first voyage had enabled him to effect considerable improvements in the procedure. The method depends upon the determination of the temperature of boiling water and the simultaneous observation of the height of the barometer. The difficulties in attaining at sea to the requisite degree of accuracy are so numerous that it is matter of surprise that trustworthy results can be obtained. There seems, however, to be now no doubt that we may trust his conclusions. Dr. Hecker exhibited his apparatus with five barometers furnished with the means for obtaining continuous photographic records of the height. One of the greatest difficulties to be contended with is the motion of the ship, for the pitching and rolling make the mercury in the barometer "pump," and the photographic trace of the barometer height is marked with regular notches. Dr. Hecker is to be congratulated on the skill with which he has overcome this and many other difficulties. His conclusions form one of the most noteworthy acquisitions to geodetic knowledge of the last twenty years.

MM. Claude and Driencourt gave an account of the use of their prismatic astrolabe. It gave me the impression that it might be an instrument of much use to geodesists.

The measurement of base lines naturally afforded an important subject of discussion, and M. Guillaume, assistant director of the International Bureau of Weights and Measures at Breteuil, gave an admirable account of the recent improvements which have been effected in the use of the Jaderin wires. It would appear that the measurement of base lines has now reached such perfection that we cannot look for any great advance in geodetic accuracy in this direction. Errors due to triangulation accumulate rapidly, and the modern practice is to measure short bases about every 200 miles. The Simplon Tunnel has been used by the Swiss geodesists as a base line, and was measured by the Jaderin apparatus. The railway company was good enough to surrender the tunnel to the geodesists for five clear days, and by means of continuous work day and night they were able to complete their task. A special form of tripod for supporting the wires was devised; it rolled along the railway lines, and in this way the labour of transporting the tripods was considerably diminished.

The national reports furnished by the several delegates were in many cases of great interest, but I can only refer to a few of them.

The work of the Swiss in the measurement of a base along the Simplon Tunnel has already been mentioned.

A proposal has been made for the collaboration of the French and Italians whereby the island of Sardinia may be linked to Corsica and to the Italian mainland.

The French delegates gave a final account of the measurement of the great arc of Peru. This work took five years, and eleven officers of the Service Géographique de l'Armée and twenty-eight under officers and soldiers took part in it. Several of the staff died of exposure and hard work in the Cordillera, and the conference received this intimation standing in token of respect to their French comrades who lost their lives in the cause of science.

I myself presented reports from Colonel Burrard, R.E., on the work in India, and from Sir David Gill, Colonel Morris, and Mr. Simms, on the geo-

[1] The observations at Cincinnati will, as I understand, be discontinued shortly.

detic survey in South Africa. The conference listened with interest to the account of the various difficulties which had been met with in Africa.

It is well known that the British South African Company, in fulfilment of the wishes of the late Mr. Cecil Rhodes, has up to the present year met all the heavy expense of that part of the survey along the thirtieth meridian of east longitude which runs through Rhodesia, but it has been found necessary for the company to effect various economies, and there was a doubt as to whether it might not prove necessary to suspend the survey for a time. Such a suspension would have proved most unfortunate, since there would have been no junction to the southward between the Rhodesian triangulation then completed as far as Gwelo and the Transvaal triangulation which begins at the Limpopo River. A surveying party under Captain Gordon, R.E., was already in the field in Rhodesia, and it was obvious that it would be much more economical to continue the work at once rather than to defer it until some undetermined time in the future. The expenditure needed for the survey from Gwelo to the Limpopo was estimated at 1600*l*. and after various negotiations in England the British South African Company offered to advance half that sum, while the Royal Society, the British Association (from a fund raised principally in South Africa for the meeting of 1905 at Cape Town and Johannesburg), the Royal Geographical Society, and Sir Julius Wernher subscribed the other half. These negotiations had to be conducted very hurriedly in order to obviate the break-up of the surveying party, but by means of the telegraph and through the exertions of Sir David Gill all obstacles were overcome, and Captain Gordon began work in June. Since the meeting of the geodetic conference I have heard from Sir David Gill that Captain Gordon is making good progress. Thus in a few months the triangulation will be finished up to and beyond the Zambezi. With respect to Northern Rhodesia, preliminary reconnaissance has been made nearly as far as Lake Tanganyika, and I have reason to hope that, although Sir David Gill is retiring from his position as Astronomer Royal at the Cape of Good Hope, the British South African Company will make arrangements for the completion of the great scientific enterprise for which they have already done so much.

At Lake Tanganyika the continuation of the survey northward will fall to the Imperial German Government. The Academy of Sciences of Berlin has appointed a committee to consider the matter, and although Dr. Helmert was not able to announce that the work would be undertaken immediately, yet I think we may be confident that the northward progress of the survey will be continued in a year or two.

In Egypt Captain Lyons is making preparations for the geodetic survey southward, and I have no doubt that when the conference next meets substantial progress will be reported there also.

In the years 1903 and 1904 the International Congresses of Geology and of Academies passed resolutions in which they asked for the help of the Geodetic Association in respect to accurate levelling and measurements of gravity with a view of throwing light on the internal distribution of masses in the earth and on the rigidity and isostasy of the crust of the earth. It was entrusted to M. Lallemand and to me to draw up preliminary reports on these subjects. M. Lallemand, whilst admitting the importance of the requirements of the geologists, could not maintain that levelling has attained to such a high degree of accuracy as to betray small movements of the land relatively to the sea, but he thought that large changes of level could be detected, and he expressed the opinion that the lines of levelling ought to be repeated at such intervals as two or three times a century. For my part I could not think that it was possible for geodesists to undertake such elaborate measurements of the direction and intensity of gravity as would fully satisfy the requirements of geologists. The repetition of the levelling of a country and systematic observations of gravity entail great expense, and the conference seemed to be unanimously of opinion that they would not be justified at present in urging on their respective Governments any increase of expenditure in these directions. Nevertheless, the wishes of the geologists will not pass unnoticed, for there can be no doubt that in future campaigns with the level and the pendulum more attention will be paid than heretofore to the constitution of the country under survey.

Before referring to the resolution on this topic which was finally adopted by the conference, I must speak of two other communications of great importance. Mr. Tittmann, superintendent of the United States Coast Survey, and Mr. Hayford, inspector of geodetic work, communicated on behalf of the United States a very elaborate discussion of the anomalies of gravity throughout the United States. The conclusions at which they arrived are of great interest to geologists, for it was shown by Mr. Hayford that, at least in the United States, the matter constituting the earth is in hydrostatic equilibrium at a depth of about seventy miles below the surface. In technical language this is the depth of isostatic compensation. In this connection Baron Eötvös, professor in the University of Buda Pest, explained his application of the torsion balance or Cavendish apparatus for determining local deviations from normality, both in the direction and in the intensity of gravity. His instrument, which we had the pleasure of seeing at the laboratories of the University, is of astonishing sensitiveness, and, so far as we can see at present, its indications are trustworthy. It would seem probable that this instrument might be used to give exactly those indications as to the distribution of internal masses of which the geologists are so desirous. The communication of Baron Eötvös was considered of so much importance that the conference directed special attention to it in the resolution which was adopted as an answer to the International Association of Academies. The Geodetic Association has at present no funds available for continuing researches with the torsion balance, but there is reason to believe that the Hungarian Government will continue to support Baron Eötvös in his researches. It may even become possible by measurements, say on Vesuvius, before and after an eruption, to find where the lava which is ejected from the crater has come from, since the displacement of large masses from beneath the mountain should be betrayed by the indications of the torsion balance.

This meeting of the conference is the last under the existing convention, which expires at the end of the present year, but it was announced that twenty of the Governments which have taken part in the existing convention have already entered into a new one for the forthcoming ten years. There is reason to believe that the Argentine Republic will also join. Indeed, Dr. Porro was at Buda Pest as representative of that Republic, and took part in our discussions.

A telegram has already appeared in the *Times*, and has been repeated in NATURE, stating that I have invited the conference to meet in Cambridge in the year 1909. This is incorrect. It is true that the association has never yet met in England, and I

believe that a meeting here would be of great value for British geodesy, but I told the conference that I had no power to give an invitation, which must come from the Government I can only now repeat the expression of the hope that the conference may meet in this country in 1909. G H DARWIN

THE FIRST "MANNED" FLYING MACHINE

OCTOBER 23 of the present year will be remembered as a red-letter day in the history of flying machines, for it was on that day that the first flying machine, constructed on the "heavier than air" principle, successfully raised itself *and its driver* from the ground several feet, and transported itself by means of its own power over a distance of eighty yards

In this his first successful flight with this machine, M Santos Dumont is to be sincerely congratulated for he has accomplished a performance which many workers in different parts of the world have been striving after for many years past and failed M Santos Dumont's machine is built on the aeroplane principle, and mounted on two wheels It is fitted with an eight-cylinder, 60 h p motor weighing about 170 lb, and drives an aluminium fan, which makes 1000 to 1500 revolutions a minute The motor is the work of the Adams Manufacturing Company, England With its driver the machine weighs about 750 lb

The aeroplane is shaped like a large T placed horizontally The short arms of the T are slightly inclined upwards, and are each composed of three compartments, like three box-kites tied together side by side At the base of the T is a large compartment, also like a box kite, and by manipulating this about a horizontal axis the upper and lower surfaces act as a powerful rudder This rudder arrangement is at the front end of the aeroplane and the operator stands on a platform midway between, and nearly on a level with, the lower surfaces of the two main inclined arms The driving fan is situated at the rear of the machine, just behind the operator, at the junction of the two main inclined arms

Now that success has rewarded this daring investigator, it is of interest to take a cursory glance at the steps which ultimately led the way to success

One naturally in the first instance, calls to mind the very interesting experiments carried out in 1893 by Herr Otto Lilienthal near Berlin (NATURE, vol xlix, p 157), because Santos Dumont's aeroplane is, generally speaking, somewhat after the style of the gliding machines used by him Lilienthal's experiments were confined to trying to learn soaring, and he employed slightly curved wings having a surface of about 15 square metres With these inclined planes, and eventually vertical and horizontal rudders, he started from the top of a hill, and after a few steps forward jumped into the air and glided sometimes 250 metres Lilienthal depended for the success of his apparatus on himself trusting to his instinct to be able to keep his balance by making the necessary compensating adjustments by moving his own centre of gravity In later experiments he employed some mechanical aid to assist him in sustaining himself longer in the air This consisted of a small machine driven by compressed carbonic acid gas, and operating a series of feather-like sails which were capable of flapping He found that occasional flapping of these wings helped him to cover longer distances

In 1895 he adopted a new principle, and instead of using one large framework, employed two smaller ones, placed parallel one above the other, this method he found distinctly advantageous (NATURE, vol liii, p 300)

About this time Lilienthal's soaring experiments began to be taken up both in this country and in America Mr Percy S Pilcher in England gained considerable experience both in the making and in the handling of these aeroplanes (NATURE, vol lvi, p 344) Unfortunately, as in the case of Herr Lilienthal, an accident during his experiments resulted in his death Pilcher, however was quite aware of the importance of using some motive power, and some time before his death proposed to employ, and actually began to make, a small and light engine, indicating about 4 h p, to drive a fan, this being considered by him as more than sufficient for flights of moderate length With this advance it was hoped that much greater distances could be covered, and a nearer approximation to a flying machine attained

There is little doubt that if Pilcher had been spared he would soon have constructed and made use of the latest and lightest form of motor, and probably been led to use the double-decked form of aeroplane adopted by Santos Dumont

By embodying the best ideas of his predecessors and using his own ingenuity to make the aeroplane a practical flying machine, Santos Dumont has advanced the science of aeronautics a very considerable step The petrol motor has no doubt helped greatly in facilitating this progress, since high-powered engines of comparatively very light weight can be constructed

In this pioneer work of navigating the air the work of Hiram Maxim and S P Langley must not be forgotten Maxim made numerous attempts to drive his flying machine at such a speed that it would be lifted off the rails on which it ran but on no occasion could it be said that this was successfully accomplished Further, it was not known whether it would capsize or not if it was set free Langley, on the other hand was undoubtedly the first to demonstrate that a machine heavier than air could be made to travel in the air driven by its own power The machines he made and launched were all "unmanned," but nevertheless much valuable information was accumulated

This the latest achievement of Santos Dumont will no doubt give a fresh impetus to the problem of flight and those who have the money and time have now before them a successful aeroplane that can serve as a starting point

THE UNIVERSITY MOVEMENT IN WESTERN AUSTRALIA

A MEETING in support of the movement for founding a university in Western Australia was held on September 7 at Perth, Western Australia The chair was taken by Dr J W Hackett, and the principal speakers included the chairman the Right Rev Dr Riley Anglican Bishop of Perth, Dr Hill master of Downing College Cambridge who is at present lecturing in Western Australia and the Speaker of the Legislative Assembly Mr Quinlan In 1904, during the Premiership of Mr Walter James, 4000 acres of land in the vicinity of Perth were set apart by the Legislative Assembly as a permanent endowment for the University of Western Australia when it should come to be formed The present income from this endowment is practically nil but its future value is likely to be considerable

Dr Hackett in his remarks explained the general

view that the university should be to enable the youth of the country to develop their faculties to their full capacity, and to permit them to compete on even terms in the practical business of life with those outside as well as inside Australia. Dr Hill, in a valuable contribution to the discussion, advocated the utilisation of existing institutions, the training college for teachers, the magnificent observatory, the museum, zoological gardens, law courts, and hospital, for the teaching purposes of the university, and suggested that many of the gentlemen holding Government appointments—the geologist, electrician, bacteriologist, &c., were eminently fitted to occupy university chairs in addition to their official duties. They did not require a palace for a start, but the men. In these days of change a great stone building was a disadvantage. His idea was to forget finance, and to coordinate the existing material. Ultimately a resolution in favour of the establishment of a university was carried with practical unanimity.

At present the higher education of Western Australia is in the hands of the University of Adelaide, which conducts the examinations and gives courses of extension lectures, and this system has worked well in the past, but naturally is only provisional. In addition, the Gilchrist trustees, through Dr R. D. Roberts, of the London University Extension Board, have for the past three years contributed to the expense of sending an annual lecturer from this country to give a course of lectures in some branch of science. These lectures are eagerly attended, and now form quite a feature in the intellectual life of the State, periodically stimulating the movement in favour of an independent university. Audiences of from 1000 to 1500 are sometimes drawn. It is difficult to say whether the lecturer or his audience derive the greater benefit. Certainly a trip round the world with a course of lectures taking one over a large part of a new continent, among the goldfields of Kalgurli, the jarrah and karri forests of the south-west, the orchards and vineyards of Armadale, is an experience fitted to make a lecturer return to his homely desk with "renewed vinegar."

The present writer recalls many a strange impression from his lecturing experience in Western Australia, a wine neither a hock, a claret, nor a madeira, something of each, but better than all; a third-class sleeping carriage on a narrow-gauge single-line railway, not yet to be found on our boasted Scotch expresses; gold in sight in the wall-face of one working not yet worked, estimated of the value of half a million sterling; a water scheme for supplying the mines, pumping a million and a half gallons daily over a watershed of 1500 feet a distance of 300 miles, in which the water spends six weeks in the pipes before reaching its destination; a camel, the only need of which in the desert is a weekly drink of water costing, maybe, 30s.; a criticism of the last night's lecture scribbled in pencil at the bottom of one mine and delivered to the lecturer in the next without coming nearer the surface than 1200 feet; a rabbit which survived two summers of drought without water; and a clergyman who took for his text "Radium."

In wishing the university movement well in Western Australia one may express the hope that it will still continue its policy of inviting outside lecturers to come and learn as well as to teach, and that many professors without portfolios may be induced to visit its shores in the future, to carry back with them an idea of a developing outside world which in the cloistered seclusion of a university is in danger of slipping from the memory.

F. S.

NOTES

THE following is a list of fellows who have been recommended by the president and council of the Royal Society for election into the council for the ensuing year:—*president*, Lord Rayleigh; *treasurer*, Mr A. B. Kempe; *secretaries*, Prof. J. Larmor, Sir Archibald Geikie; *foreign secretary*, Mr Francis Darwin; *other members of the council* (the fellows whose names are printed in italics are not members of the existing council), *Lord Avebury*, *Sir Benjamin Baker, K.C.B.*, *Dr H. F. Baker*, Prof. J. Norman Collie, Prof. Wyndham R. Dunstan, *Prof. David Ferrier*, *Prof. Sydney J. Hickson*, Sir William Huggins, K.C.B., Prof. E. Ray Lankester, Mr H. F. Newall, *Dr Alexander Scott*, *Prof. A. C. Seward*, *Prof. W. J. Sollas*, Prof. E. H. Starling, *Prof. Silvanus P. Thompson*, and *Dr A. D. Waller*.

THE Royal Society's medals have this year been adjudicated by the president and council as follows:—the Copley medal to Prof. Elias Metchnikoff, for the importance of his work in zoology and in pathology; the Rumford medal to Prof. Hugh Longbourne Callendar, for his experimental work on heat; a Royal medal to Prof. Alfred George Greenhill, for his contributions to mathematics, especially the elliptic functions and their applications; a Royal medal to Dr Dukinfield Henry Scott, for his investigations and discoveries in connection with the structure and relationships of fossil plants; the Davy medal to Prof. Rudolf Fittig, for his investigations in chemistry, and especially for his work in lactones and acids; the Darwin medal to Prof. Hugh de Vries, on the ground of the significance and extent of his experimental investigations in heredity and variation; the Hughes medal to Mrs. W. E. Ayrton, for her experimental investigations on the electric arc, and also upon sand ripples. The King has approved of the award of the Royal medals. The medals will, as usual, be presented at the anniversary meeting on St. Andrew's Day (November 30). The society will dine together at the Whitehall Rooms on the evening of the same day.

Two events during the past few days have shown that men of science recognise the ability of women to originate and carry out scientific research and inspire others with their spirit. One is that on Thursday last the Royal Society awarded the Hughes medal to Mrs. W. E. Ayrton for her experimental investigations on the electric arc and also upon sand ripples, and the other event is the first lecture delivered at the Sorbonne on Monday by Mme. Curie, who has succeeded the late Prof. Curie in the chair of general physics of the University of Paris. Both Mrs. Ayrton and Mme. Curie originated and carried out their scientific investigations unaided, and the tacit acknowledgment just made of their creative capacity—essential to work of this kind—is interesting and significant. Though some of Mrs. Ayrton's experiments on the electric arc were made in the laboratories under Prof. Ayrton's charge at the Central Technical College, it was to her alone that the conception and carrying out of the experiments were due, as well as the original speculations deduced from the results. The Royal Society, by placing Mrs. Ayrton's name alone, and not bracketed with that of a man, in the list of medallists for this year has manifested its recognition of individual work by a woman. The Davy medal was awarded by the society in 1903 to Prof. Curie and Mme. Curie jointly, for their researches on radium, though the published work on the subject shows that the discovery of radium was due to Mme.

Curie alone. But however this may be, it should be gratifying to those who have worked for the extension of opportunities for intellectual work by women to find that the scientific world is prepared to acknowledge merit without distinction of sex. The logical result of the action of the Royal Society and the University of Paris is that women should be eligible for election into any society or academy that exists for the purpose of extending the boundaries of natural knowledge.

A MEETING of the executive committee of the British Science Guild was held at the rooms of the Royal Society on November 2, Mr. Haldane, M.P., president of the Guild, in the chair. In addition to the ordinary business the following matters were under consideration:—a memorandum on the application of improved methods in agriculture, an interim report of a subcommittee of the Guild on the amendment of the British patent laws, the appointment of local committees of the Guild in industrial centres, and the proposed anthropometrical survey.

DR. J. GUNNAR ANDERSON has been appointed director-general of the Geological Survey of Sweden in succession to Dr. A. E. Tornebohm, who retires.

THE Swiney lectures on geology in connection with the British Museum (Natural History) are being delivered this year by Dr. R. F. Scharff, who commenced on Monday a course of twelve lectures on the "Geological History of the European Fauna" in the lecture theatre of the Victoria and Albert Museum, South Kensington. The lectures will be given on Mondays, Wednesdays, and Fridays, at 6 p.m. Admission to the course is free.

DR. POIRIER, professor of anatomy at the Paris Academy of Medicine, has proposed the establishment of an organisation to combine the efforts of French investigators who are studying cancer. It is hoped that France will before long have an institute similar to that in connection with our Imperial Cancer Research Fund, and to corresponding institutions in Germany and the United States. Dr. Henri de Rothschild has contributed 4000*l.* to the funds of the proposed league against cancer.

THE preliminary forecast of the indigo crop of Bengal for 1906 is given in the *Pioneer Mail*. It appears that, owing to the competition of the synthetic dye, the area under indigo has contracted very rapidly. The cultivation is being gradually abandoned in Lower Bengal. The total area sown this year is 138,300 acres, against 170,700 acres of last year, and 223,100 acres of 1904. Of the important districts, Saran reports 62 per cent. of a normal outturn per acre, Darbhanga reports 57 per cent., and Muzaffarpur 33 per cent., while Champaran reports only 27 per cent. The estimated outturn per acre for Lower Bengal, including the minor Behar districts, is 67 per cent. of a normal crop, and that for North Behar, including Monghyr, only 42 per cent. The average for the province comes to 46 per cent., against 47 per cent. The director of agriculture, however, thinks the district officers' estimates are unduly pessimistic.

COMMANDER R. E. PEARY, who has been in the Arctic region since July, 1905, when he left New York on the steamer *Roosevelt* to make a further attempt to reach the North Pole, arrived in Battle Harbour, Labrador, on November 3, and dispatched a message announcing his return. From this it appears that the expedition wintered on the north coast of Grant Land, somewhat north of the *Alert's* winter quarters. In February the sledge party went north *viâ* Hecla and Columbia, but was delayed by open water between 84° and 85°. Beyond 85° a six days' gale disrupted the ice, destroyed the caches, cut off communication with the supporting bodies, and drifted the party due east. Journeying over ice, farthest north was reached in lat. 87° 6', while the ice was drifting steadily eastward. The north coast of Greenland was arrived at afterwards, and by travelling along the Greenland coast the ship was regained. A sledge journey was then made to the west, and the message states that the party "completed the north coast of Grant Land, and reached other land near the hundredth meridian." Further details about the movement of the ice and the land to the north of the hundredth meridian west of Greenwich, that is, north of the American mainland, will be awaited with interest. The most northerly point reached—lat. 87° 6'—is nearly three degrees farther north than Commander Peary attained in 1902. The Duke of the Abruzzi's expedition reached lat. 86° 33' 49", in long. 64° 30' E., in 1900.

THE promise of an interesting and useful addition to the local museums in the London district has been furnished by the spirited action of the Tottenham Local Board. In 1892 the Board purchased the fine "Queen Anne" mansion known as Bruce Castle from Mr. Joshua Pedley at the price he had given for it, 15,000*l.*, toward which sum he contributed 700*l.*, in the hope that some day the house would become the home of a museum for Tottenham. The estate included twenty acres of garden and timbered land, which was soon thrown open as a public park. The idea of a museum having been grasped, many specimens and offers of aid came in from neighbours and friends. By gift and as a result of a public subscription several important collections were acquired. Especially worthy of mention are the long series of birds, small mammals, and insects in cases and cabinets made by Mr. H. W. Roberts, formerly a resident in Tottenham, a collection of minerals and fossils formed by Mr. Penstone, a friend of John Ruskin, and the collections of fossils and wax models made and lent by Mr. H. J. H. Smedley. Mr. Smedley is acting as honorary curator, and has generously devoted much time and skill to getting the collections into a fit state for public exhibition. Other important gifts have been made by Mr. C. C. Knight, the Hon. Walter Rothschild, Mr. Ruck, Mr. Currie, and others. The museum was publicly opened by Mr. W. W. Lewin, chairman of the libraries committee, and Councillor Knight on October 26. Mr. Smedley is responsible for the scheme of the museum, which will embrace a purely local collection of Middlesex natural history and illustrations of ancient Tottenham, while the educational aspect will be kept well in view, including exhibitions of living animals and plants designed to encourage observation at first hand in the field amongst the young people and school pupils in the district.

IN commemoration of the forty years' reign of H.M. King Charles I. of Rumania, an exhibition is now being held at Bucharest, where the fifth Congress of the Rumanian Association of Science also assembled during last month, and was attended by more than four thousand members. Judging from the importance of the papers read and the discussions following, there is noticeable a decided advance in the appreciation of the value of education on the part of the Rumanians. The congress was divided into ten sections, the best attended being the one dealing with educational science, numbering more than three thousand members, including university professors and teachers of all classes. Great attention was given in this section to the question of extending the

number of hours at schools prescribed for physical training and military drill The economic science section was also well attended, and great interest was attached to the papers read dealing with the betterment of the status of the peasantry, a subject which engages the attention of all political parties of the country The outcome of this meeting has been the inauguration of a special society, starting with above two hundred members and having as its object the thorough investigation and discussion of the social and economic problems of Rumania One of the characteristic features of the congress was the fact that, for the first time, the clergy, as a body participated by forming a separate section, and among other questions discussed the scientific aspects of religious teaching It is believed that the industrial and commercial section will grow in importance in the near future Among the other sections in which good work was done, mention may be made of the medical, physical, and chemical sections On the whole more than 160 papers were read Much credit is due for the success of the congress to the president, secretaries, and council of the association who, through their energy and zeal, have secured a promising future for their association in the welfare of which the King and Queen of Rumania and the Royal Family take a great interest The next congress will be held in September 1907, at Focsani

CORALLINES and burrowing-sponges, illustrated by a plate reproduced from Johnston together with an account of the abnormally grown beak of a bird (presumably a rook, although no statement to that effect is made in the text) and sundry notes and observations on natural history, form the chief zoological contents of the *Museum Gazette* for October

THE issues of *Naturwissenschaftliche Rundschau* (published at Brunswick) for October 11 and 18 contain articles on "embryonic transplantation" (*embryonale Transplantation*) and the present state of our knowledge of the "rarer earths" Embryonic transplantation it will be remembered, was the name given by G Born of Frankfort-on-Maine to the operation of grafting portions of one young larva of a newt or frog on the body of another, whereby two-headed or double tailed monsters were produced In the opinion of the author Prof H Spemann of Wurzburg the continuation of such experiments would probably shed light on certain obscure biological problems In the course of his article on the rarer earths, Dr R J Meyer of Berlin points out that scandium, which was found in 1879 in gadolinite and euxenite, and appears never to have been seen again in that state, is the scarcest member of the whole group, if, indeed, it be rightly included therein

In the October issue of the *American Naturalist* Mr J C Herrick communicates an illustrated account of the results of his investigations into the mechanism of the dental, or "odontophoral," apparatus of the gastropod *Fulgur* or *Sycotypus canaliculatus* Especial attention was directed in this investigation to the discovery of the manner in which the gastropod perforates the shells of other molluscs The mechanism of the "radula," or dental apparatus corresponds, in the case of this genus at any rate, to the action of a chain-saw, with the restriction that the sawing action is accomplished only during the return stroke The buccal cartilage forms a stiff framework and a grooved passage for the radular sac and the retractor muscle of the dental ribband The muscles for protruding and retracting the radula are of very different power, owing to the fact that, from the backward direction of the teeth, the rasping is accomplished during the return pull The author might have added that the chain-saw action is continued during the process of feeding The second article, by Mr L B Walton, deals with the microscopic fresh-water annelids of the family Naididæ obtained at Cedar Point, Ohio

To the October *Zoologist* Mr R B Lodge contributes an interesting article on pelicans in Eastern Europe illustrated by the reproduction of a group of *Pelecanus crispus* on an island in an Albanian river In the case of *P onocrotalus* the parents have been stated to feed their young from the pouch, but in the species observed by the author the young birds were seen to thrust their heads into the parental throat much below the opening of the pouch, thus resembling young cormorants The nests were generally in groups of six or eight, the majority mere flat rings of sticks on the ground, but a few large structures of sticks some 2 feet in height, and very similar to cormorants' nests In a second article Mr Harvie-Brown discusses the best method of identifying the nests of the various species of wild ducks by means of the down with which they are lined, and shows that exact observations are necessary before our information on this subject can be regarded as anything near complete The past history of the kite in Somerset forms the subject of a communication by Mr F L Blathwayt, while Mr B F Cummings discusses Goldsmith's qualifications as a naturalist In the "Notes" column Mr Harvie-Brown is enabled to announce, from the evidence of notes and a sketch communicated by the Duchess of Bedford that the "sea monster" recently seen in Loch Broom, on the Cromarty coast was almost certainly a basking-shark

GUMMOSIS of sugar-cane plants forms the subject of Bulletin No 3 issued from the pathological division at the experiment station of the Hawaiian Sugar Planters' Association The author Mr N A Cobb, was the first to ascribe the disease to a bacterium, this opinion has been confirmed and the organism has received the name of *Bacterium vascularum* Diseased plants can be detected by the presence of dwarfed shoots bearing narrow, dried-up leaves also on cutting the stems gum oozes out of the fibres, thus furnishing a convenient means of testing sets intended for propagation Some varieties were found to be immune to inoculation, and it has been suggested that immunity is correlated with acidity of the sap

A FIFTH instalment of new or noteworthy Philippine plants identified by Mr F D Merrill forms supplement III to the first volume of the *Philippine Journal of Science* *Pachycentra formicana*, an epiphytic shrub forming a new species of a Malayan genus, is characterised by bulb-like roots inhabited by ants, *Sundra supa* a leguminous tree, yields timber serviceable for naval construction, and an oil suitable for making paint and varnish Several new species of Loranthus are reported, also an Anthoxanthum similar to sweet-scented vernal grass and a Poa related to *Poa pratensis* The writer has drawn up two lists of plants the one illustrating the floral relationship between the Philippines and the Celebes, the other showing the northern element in the Philippine flora

THE curator of the botanic station in Dominica refers in his annual report for 1905–6 to the large demand, constituting a record, for young plants, the chief requests being for cacao and lime plants, a considerable number of budded orange plants, mostly of the Washington navel variety, was also supplied In the matter of

manurial experiments with cacao now extending over four years, a most striking result is noted for the plot mulched with grass and leaves from which the yield per tree is higher than from the plot manured with phosphate blood, and potash, and 77 per cent higher than from the unmanured plot

A SERIES of new African species of plants determined by various authorities appears as "Diagnoses Africanæ, XVIII," in No 7 of the *Kew Bulletin* A Cissus collected by Mr Dawe in Uganda is morphologically interesting on account of its bearing so-called "pearl-glands" that are regarded as food-bodies for ants Mr G Massee contributes descriptions of a few new fungal species from the Gold Coast and elsewhere, as well as an article on potato-leaf curl This disease is perpetuated by mycelium in the tubers or by conidia in the soil, it is also noted that the same disease occurs on tomatoes An article by Mr W J Bean relative to a visit to famous Scottish gardens furnishes a good account of the trees, especially conifers, that have been successfully grown in this northern, but by no means rigorous, climate

WE have received from the Biological Laboratories Massachusetts Institute of Technology, "A Statistical Study of Generic Characters of the Coccaceæ," by C E A Winslow and Anne F Rogers A number of characters, such as average dimensions, manner of grouping, staining reactions, vigour of surface growth, acid production in dextrose and lactose broth, formation of nitrites and ammonia in nitrate solution, and chromogenesis, were determined for 500 cultures from various habitats and tables are given showing the frequency distributions for single characters and pairs of characters These tables indicate with great clearness the extreme variability of the Coccaceæ and the impossibility of laying down hard and fast boundaries for the classification of individuals At the same time, the authors show that certain natural types are apparent when the characters of the aggregate, and not of the individual are considered e g the relative frequencies of different forms of grouping, the reaction to Gram stain, the vigour of growth the rapidity of formation of nitrites or ammonia, and the most frequent colour of the pigment formed On the whole, they find that the last-named character is of most importance, and most highly correlated with other characters The work is an interesting application of statistical methods (of a very simple kind) to the difficult problem of the classification of the bacteria

THE October number of *The Central*—the Central Technical College Old Students' Assosociation magazine—includes an interesting illustrated article by Mr Bernard Dunell on suction gas for marine propulsion Mr Dunell describes Messrs Thornycroft and Co's efforts in the direction of a satisfactory gas propelled barge and also of a launch, and the results which have been obtained The writer then goes on to describe some novelties in the construction of the engine frame and in the method of connecting the cylinder trunks to it, the object being to do away with heavy bolts, and also to make the operation of disconnecting the cylinder head as simple and as quick as possible On the question of fuel for engines up to 250 horse-power anthracite or coke is used, the reason being that a cleaner gas is obtained more readily and with a simpler apparatus than is possible with bituminous coal The writer states that Messrs W Beardmore and Co are just completing two marine gas engines and producers of 500 horse-power and 1000 horse-power respectively, and in these cases ordinary bituminous coal will be used The results on these large units will be awaited with interest both from the coal point of view and also from the "gas *versus* steam" for marine work Mr F Mann Langley's contribution on electric train lighting deals with a subject of which in a general way very little is heard Although the electric lighting of trains is now taken as a matter of course so little is known about it that the author's description of the present-day methods of the generation regulation and the switching in and out apparatus between battery and dynamo is very welcome Other papers in the same issue on the evolution of the incandescent electric lamp, by Mr A S T Akerman and single phase electric traction, by Mr I Calisch are of interest, the former especially as giving a description of the "Linolite" lamp

WE have received from Messrs A Guinness Son and Co, Ltd, of Dublin a copy of part ii of vol i of the Transactions of the Guinness Research Laboratory printed for private use The principal researches carried out at the laboratory of which Dr Horace T Brown is director and published in this part are an exhaustive investigation of the nitrogenous constituents of malt which are soluble in water, and a study of the water soluble poly saccharides of malt

A REPRINT has been received of a lecture on "The Early Use of Iron," delivered by Mr Bennett Brough before the Iron and Steel Institute at Glasgow in March and published in No 1 of the journal of the institute (pp 233–253) The lecturer summarises recent investigations of the earliest records to be found of the use of the metal An interesting account is given of the use of iron in ancient Egypt Syria India and Europe and of primitive methods of working iron which still survive in India and among the negro races of Africa

THE Nobel lecture for 1906 delivered by Prof Philipp Lenard on May 28 before the Royal Swedish Academy of Sciences has been published under the title "Ueber Kathodenstrahlen" by the firm of J A Barth of Leipzig (pp 44 price 1 20 marks) It contains an admirable historical account of the development of our knowledge of kathode rays and allied phenomena, from the time of the early experiments of Crookes in 1879 to the present day The most important stages in the investigation of the rays are clearly defined and the story of the growth of the modern electronic theory of matter is told in a manner at once comprehensive and free from technicalities The account given by Lenard of the genesis of his own experiments in this field is of no little historical value A useful chronological review of the literature comprising in all fifty-five papers published between 1860 and 1906 is appended

AN investigation of the dimorphism of calcium and barium carbonates has recently been described by H F Boeke in the *Zeitschrift für anorganische Chemie* (vol l pp 244–8, August 31) It is shown that barium carbonate when heated in an atmosphere of CO exhibits a sudden arrest of temperature at 811° This temperature, which varies only by a degree or two when the rate of heating is altered represents a true inversion point for the dimorphous carbonate The reverse change takes place less readily, but is accompanied by a marked liberation of heat, when cooled rapidly the arrest point was as low as 761° but slower cooling showed an arrest at 795° approximating towards the temperature of the sharply defined arrest point in the heating curve In the case of

calcium carbonate there is a fairly definite temperature, $470° \pm 3°$ C., at which arragonite passes into calcite, but the change in this case is not reversible, and even at low temperatures calcite appears to be the stable, and arragonite the labile form.

MESSRS. F. DARTON AND CO., Clerkenwell Optical Works, have sent us a copy of the latest issue of their list of electrical novelties. The catalogue may be commended to the attention of those who are interested in the application of electricity to domestic, medical, and other purposes.

MESSRS. F. E. BECKER AND CO., Hatton Wall, London, have submitted for our inspection a specimen of their "Nivoc" patent stencil. The stencil is designed to assist young students of science in making drawings of apparatus, and will be found of service for this purpose. At the same time the adoption of stencils of this kind will deprive pupils of the practice necessary to enable them to develop the power of rapid, unaided sketching which, as Huxley long ago pointed out, is essential to the student of science.

A SECOND edition of Prof. A. E. H. Love's "Theoretical Mechanics: An Introductory Treatise on the Principles of Dynamics" has been published by the Cambridge University Press. The first edition of the work was reviewed at length in our issue for June 23, 1898 (vol. lviii., p. 169). It is only necessary to state that the changes which have been made in the present edition are for the most part of the nature of a re-arrangement of the order of the material. The consequence is that the theory has been presented in a less abstract fashion, and long preliminary discussions have been avoided.

A SECOND edition of the late Prof. P. Drude's "Lehrbuch der Optik" has just been published by Mr. S. Hirzel, Leipzig. The text has been revised, and forty pages have been added to the book in order to bring under consideration the work in magneto-optics and related subjects done since the original edition appeared six years ago (see NATURE, October 18, 1900, vol. lxii., p. 595). The manuscript of the new edition was completed and partly printed before Prof. Drude's lamented death, but Mr. E. Kiebitz has seen it through the press. The work has now an index.

THE twelfth volume of the new series of the *Reliquary and Illustrated Archaeologist* has now been published by Messrs. Bemrose and Sons, Ltd. It consists of the four quarterly numbers issued during the present year. The first of these parts includes a contribution by Mr. J. Patrick to the series of papers dealing with the sculptured caves of East Wemyss, in which the Factor's Cave is described. The April number contains an illustrated article by Mr. R. Quick entitled "Notes on the Evolution of the Means of Transport by Land and Water." The most primitive means of transport by land is stated to be by means of tent poles and skin tents, but it would be hard to prove that this method was primitive either in time or in culture, especially as the author credits "prehistoric man" with "a conveyance of logs of wood bound together by withes and carried in the hand somewhat in the manner of the Chinese sedan chair." The July number includes two interesting papers by Mr. J. Charles Wall on Lastingham, one, "Pure Norman," describes the unique example of a pure Norman crypt free from any intrusions of later architecture, and the other, "Lastingham Relics," tells of some of the treasures, mainly the sculptured stones, to be found in the crypt. The concluding part is perhaps of less interest to the man of science. It contains, with other papers, an account by Charlotte Mason of the characteristics of Blythburgh and its church, and a short paper by Sophia Beale on the evolution of the ancient lamp.

OUR ASTRONOMICAL COLUMN.

THE CALORIFIC RADIATION OF THE SUN.—Further results relating to the intensity of the solar calorific emissions are published in No. 17 of the *Comptes rendus* by MM. Millochau and Féry. Using the instrument described in their former note, and considering only the centre of the solar disc, they obtained measures at Meudon (altitude = 150 m.), Chamonix (altitude = 1030 m.), and the summit of Mont Blanc (altitude = 4810 m.). Accepting the emissive power as being equal to unity, these gave 4820°, 5140° and 5560°, respectively, when standardised by the electric furnace. All these measures were obtained when the sun was near the zenith, and the observers give a table showing the hourly variation of the apparent temperature from 8 a.m. to 6 p.m.

The maximum observed temperature on the summit of Mont Blanc was 5590° absolute, and, roughly correcting for the atmospheric absorption, this gives the final result as 5620° absolute.

THE SYSTEM OF 61 CYGNI.—In No. 4128 of the *Astronomische Nachrichten* Prof. Barnard discusses a series of measures of the double star 61 Cygni which he made on 144 nights between August 7, 1900, and November 12, 1904. These measures were undertaken for the purpose of testing Dr. Wilsing's hypothesis as to the existence of an unknown dark body in the system of this star. This observer found that his photographic measures indicated an apparent periodic oscillation in the distance between the two components of about 0".3, taking place in twenty-two months. If this oscillation were real its effect on the measures of the parallax of this star would be considerable, and might account for the large differences already obtained by various observers.

Prof. Barnard's results do not, however, confirm the hypothesis, although the observations extended over twice the interval of Dr. Wilsing's supposed period. The distance between the two components does not appear to be affected by any periodical variation, and only in one case does the distance difference exceed the mean by so much as one-tenth of a second of arc. It seems evident, therefore, that some cause other than that of a disturbing body will have to be found for the differences observed by Dr. Wilsing.

THE CAPE OBSERVATORY.—In his report of the work performed at the Cape Observatory during the year 1905, Sir David Gill states that the two underground azimuth-marks of the new transit circle are now working satisfactorily, and that the observations with this instrument show a systematic diurnal variation of azimuth amounting to about +0.02 second. When the observations of circumpolar stars are sufficiently discussed to determine the absolute variation of the azimuth-marks, it seems possible that these may prove sufficiently stable to permit of the determination of the horizontal component of Prof. Chandler's change of latitude. The automatic arrangements for regulating the pressure and temperature inside the sidereal clock-case are now perfect, the temperature never varying from 75° F. by more than one-tenth of a degree. The work for the Astrographic Chart and Catalogue was nearing completion at the end of 1905, and during that year 148 catalogue plates, containing 1944 standard and 112,080 other star images, were measured.

MINOR PLANETS.—In No. 4128 of the *Astronomische Nachrichten* Dr. Bauschinger publishes the numbers which have been allotted to the recently-discovered minor planets. From this list we see that the total number, up to June 21, 1906, was 601, and that thirty-two new ones were discovered between July 30, 1905, and that date, mostly at the Heidelberg Observatory. The same publication also contains a list of the names allotted to various minor planets between No. 459 and No. 562.

DESIGNATIONS OF NEWLY-DISCOVERED VARIABLE STARS — The permanent designations allotted to recently-discovered variable stars by the Commission of the A G Catalogue of Variable Stars are published in No 4127 of the *Astronomische Nachrichten* The table given also shows the position for 1900, the precession corrections, and the range of magnitude of each object

THE BOLOGNA OBSERVATORY —We have received from the director of the Bologna Observatory, Prof Rajna an interesting account of the history of the observatory of its present condition, and of a projected re-establishment on a new site Founded in the year 1712 the observatory was a prominent one in the astronomical world at that time, but at the end of the eighteenth century a decadence set in and, with the exception of the period 1855–1865, when Respighi was director, has continued ever since The instruments are out of date or incomplete, and the only work prosecuted is the computation of ephemerides Prof Rajna has, however, elaborated a scheme whereby the observatory might be installed in an existing building and re-fitted with new instruments at an estimated cost of about 147,000 lire (about 5800*l*) and to this end appeals for help in carrying out his project

RESEARCH IN INDIA[1]

IT must be confessed that the Englishman at home takes little interest, other than political, in his Indian Empire The fact has been noticed by the Hindus themselves We do not compare favourably with the Dutch, for example, who are keenly interested in every aspect of their possessions in the East Yet the scientific importance of India (a big slice of the globe comes under the name) is in many ways unique, and to the sympathetic and imaginative mind its varied yet homogeneous population supplies an inexhaustible fund of suggestion for the study of man Much has been done, sporadically since the days of Sir William Jones but scientific research in India has never been adequately organised The antiquities and languages of India have received comprehensive attention but the most remarkable religion of the world has depths still unfathomed, the institutions and social habits of the people are not yet fully understood important documents like the Tantras still remain untranslated though the task is a simple one and its results would be of great value Meanwhile the Hindus are the people who thousands of years ago, said—as some think—the last word on philosophy It is curious to note how frequently the European thinker ends his course in some system long ago familiar to the Hindu 'The immobility of the East so strangely contrasting with our feverish civilisation may perhaps contain the solution of a problem which still perplexes us – how to live

The memoirs here noticed represent a varied range of research in biology ethnology the history of science palæography and religion, in which Englishmen, Mohammedans, Hindus, and a Belgian Jesuit have taken part Mr G Muhammad gives new data on the customs and traditions of the people of Gilgit a dependency of Kashmir where polo is the national game and a noble family exists claiming descent from Alexander the Great These people as others of the Hindu Kush possess a harvest ceremonial of great interest, and the present paper gives some well arranged additions to Sir George Robertson's account of the subject

The paper on the Bhotias tells us a good deal about a little-known people Their culture is partly Hindu and partly Tibetan With the exception of the Jethoras, they are tradesmen by instinct and education The system of house-connections was their business method, until the treaty of Lhasa in 1904 changed the conditions of trade The national institution of the *rambang* or village club presents features of importance for the study of similar customs In their marriage ceremonies there is a mock capture of the bride The distinction between children and adults is marked, in language and custom, by the permanent teeth After the burning of a corpse a bone is taken from the pyre and placed with much ceremony in what are known as "ghost boots," while advice is given to the departed spirit as to the road he has to take

The most considerable of these papers is that by the late Father Dehon, S J , a missionary who knew the Uraons well He might have compiled a valuable monograph on the people with whom he had worked for so many years had he lived His notes reveal a liberal and scientific mind and contain much new and already elaborated information to supplement Dalton and Risley The Uraons or Oraons are one of the most interesting branches of the so-called Dravidian race One or two details will show what the reader may expect to find in the paper More than evil spirits they fear the evil eye and the 'evil mouth' and the *palkhausna* rite to obviate the evil results of envy is in constant use Father Dehon is particularly complete and lucid in his account of their theistic and spiritualistic beliefs Each dead man has two shades a light and a heavy, the latter goes to *Markha* (heaven) the former remains among the living Their ancestor worship is full of pathos and affection Human sacrifice, the author assures us still occurs in spite of the vigilance of the authorities Waifs and strays tramps and strangers, are the victims and the object of the sacrifice is to promote the success of the crops The susceptibility of these natives to hypnotic influence is remarkable, and considerable use of this peculiarity is made in their religious practices We are even told that 'in a Mission School in Chota Nagpur every time the boys sang and beat the *tomtom* together they constantly fell into trances and would run like cats along the rafters of the school and do all kinds of wonderful things ' In the *dhumkuria* or dormitory in which the village boys sleep there is an organised system of bullying the object of which is to make them hardy members of society What would our educationists say to this? The *panch* is the whole community represented by the older members and forms their republican chamber There is a proverb repeated on all important occasions 'above God below the *panch* '

Two papers owe their material to the late Tibetan expedition Some Tibetan scrolls from Gyantse contain interesting accounts of Buddhist saints but do not seem to add anything new Mr Francke argues that the beautiful Tibetan script is derived from the Kashgar Brahmi characters To one whose acquaintance with the ordinary Devanagari Sanskrit alphabet is but recent the author seems to make out a good case for his theory

Mr Stapleton's study in primitive chemistry is extremely interesting He traces the connection between savage magic and mediæval alchemy with special reference to the process of obtaining sal-ammoniac from burnt hair His other paper with Mr Azo deals with the materials and apparatus of alchemy in the eleventh century and is worth the attention of chemists who are interested in the origins of their science It is chiefly written round an Arabic book *Inter alia* he shows that importance was attached to weights in chemical experiments 700 years before the time of Black and Lavoisier

Marine zoologists will find new examples of Pedunculata described and illustrated in Mr Annandale's paper The Ashrafpur copper plates reveal the existence of a hitherto unknown line of Buddhist kings in east Bengal

There are some good plates in the volume The press correcting is at times annoying there are too many misprints, and it is confusing to find two papers each commencing on p 93 one ending on p 119 the other on p 127 while the succeeding paper begins on p 121

NATURAL HISTORY IN NATAL

WE have the pleasure of congratulating the trustees, and the colony generally, on the appearance of the handsomely illustrated report mentioned below[1] which inaugurates what is practically a new era as regards scientific progress in Natal. As the museum was only opened to the public on November 30, 1904, the report is devoted almost entirely to an account of the building and the condition and extent of its collections at that date. It is, however, satisfactory to learn that, under the direction of Dr. E. Warren, the institution is already of considerable educational value to the colony, and that it promises to be still more so in the near future. One of the questions which, as in all such cases, exercised the minds of the authorities at starting was whether the museum was to be solely devoted to local exhibits or was to contain a representative general series. So far as zoology is concerned, the question has been decided in favour of the latter alternative, and it has been also settled that local and foreign specimens are in the main to be exhibited in one series. Whether these are the most satisfactory conclusions it is not for us to say; but we may at any rate welcome the announcement that the antelopes and other ungulates, which form the most striking—and at the same time a fast disappearing—feature in the South African fauna, are to have a separate gallery for their display. Good progress has already been made with this portion of the collection, and, if we may judge by a photograph of one portion of the "ungulate room," the mounting of the specimens, as exemplified by a group of waterbuck, and the ample amount of case-room provided, will render this part of the collection as attractive and striking as its representative in our own Natural History Museum. We are glad to see that the example set by the latter institution of mounting the specimens either on artificial ground-work or on earth-covered (in place of polished sycamore) stands has been adopted by the director, and we may express the hope that no efforts will be spared to render this series as complete as possible before it is too late.

As regards the educational function of the museum, it was decided to defer the establishment of lectures and classes until such time as a special commission had finished its sittings and issued its report; but it is proposed that the institution should eventually take its share in a large scheme of technical education in such subjects as zoology, botany, and geology.

In issuing a new scientific serial under the title mentioned below[2] the authorities of the Natal Museum are undoubtedly doing good service to the cause of biology and geology throughout the world, more especially as one of its great features is the full and sufficient illustration of the new species from time to time described. In this latter respect the trustees are setting an excellent example of wise liberality, for one of the crying evils of the present day is the continual flood of descriptions of alleged new forms with inadequate or no pictorial illustrations. By means of the large number and superb execution of the plates accompanying the issue before us naturalists will be able to form their own opinions of the validity of the new species described, and it is sincerely to be hoped that no financial conditions will be allowed to bar the maintenance in succeeding issues of the high standard adopted in the first number. There appears, however, to be every reason to hope that the present standard will be maintained, as it is stated in the introduction that such is the express wish of both the trustees and the publishers. It is expected that about two parts (of variable size) will be published yearly. From the number of illustrations the price is naturally somewhat high (10s. in the case of the present issue).

The editor has been fortunate in securing for his opening article a communication on South African fishes, in the course of which Mr. C. T. Regan describes a new South African beaked shark differing from typical species of Pristiophorus in possessing six in place of five gill-slits. This difference is regarded by the author as of generic value, and the new generic term Pliotrema is accordingly proposed. Several other new fishes are described and illustrated by Mr. Regan. With the exception of one on the abnormally elongated and spirally twisted hoofs of an African sheep, the other articles are devoted to invertebrates. Mr. E. A. Smith, for instance, contributes a list of South African marine molluscs, lengthened by the addition of some new species of his own, while other writers discourse on Natal zoophytes and divers other representatives of the African marine fauna, and the editor describes a "Myxosporidium" from an African rotifer.

Once more we repeat our sense of the obligations under which biologists and geologists are placed by the liberal and progressive policy of the trustees of the Natal Museum.

R. L.

WEIGHTS AND MEASURES REGULATIONS.[1]

UNDER the Weights and Measures Act, 1904, the Board of Trade is required to make regulations with respect to weights, measures, and weighing and measuring instruments used in trade. These regulations, when made and laid before Parliament, are to be of general application throughout the United Kingdom, and will have the force of an Act of Parliament. The Board of Trade has accordingly prepared a code of regulations, which are, however, at present in draft form only.

These new regulations are a considerable improvement on the various local codes which they are intended to replace on January 1, 1907. They are much more definite and more readily understood than the somewhat oracular Model Regulations of 1890. The principal innovations are the abolition of cased weights, a requirement that pewter measures shall contain at least 80 per cent. by weight of tin, the restriction of the linear dimensions of dry measures of capacity to certain specified limits, the prohibition of wooden measures turned from the solid block, and the exclusion of counter weighing machines constructed on the accelerating principle. All these are steps in the right direction, and it is not anticipated that they will entail any injustice either to manufacturers or tradesmen.

A provision which will possibly meet with some objection is clause 23, which requires that the weighing instruments used by chemists and tobacconists shall satisfy the requirements of class A. This regulation, in conjunction with No. 87, would appear to prohibit these traders from using counter weighing machines and to require them to use either beam-scales or balances. There may be some exemption for machines already in use, but the important clause (No. 19) dealing with this matter is unfortunately rather loosely worded, and admits of different interpretations. It is by no means certain, however, that this prohibition, although virtual and indirect, is not *ultra vires*, as the power conferred on the Board of Trade by section 5 (1) (*d*) of the Act relates to limits of error, not to forms of weighing machines, and would appear to be exceeded here. Bearing in mind the fact that the most vexatious regulation of the 1890 code was one which the law officers of the Crown subsequently declared to be invalid, it would be a matter for regret if the excellent series of regulations now under consideration were marred by the inclusion of any provision of doubtful legal sanction.

The limits of error tolerated do not differ much from the old allowances. As regards the tests prescribed by the department under section 5 (1) (*c*) of the Act, the mode of applying these might be more precisely defined. For instance, a 1 lb. balance is required to be correct within 0.2 grain, and unless the inspectors are to be provided with standard weights of unusual accuracy it would be only fair to prescribe strictly the method of testing to be observed in such a case. The regulation on this subject (No. 85) appears somewhat vague.

In framing these proposed regulations the Board of Trade has had the advice of a committee of experts presided over by Mr. W. R. Bousfield, K.C., on which the department was represented by Major P. A. MacMahon, F.R.S.

THE INTERNAL ARCHITECTURE OF METALS[1]

IT has been cynically remarked that to deliver a successful scientific lecture to a cultured audience it is necessary to divide the lecture into three parts The first part should be understood both by the audience and the lecturer, the second part by the lecturer and not by the audience, and the third part neither by the audience nor by the lecturer

If the foregoing dictum were true, the speaker found himself in a paradoxical position The object of the discourse was to make the subject under consideration as clear as possible throughout, hence the more nearly this object was achieved, the more unsuccessful the lecture The title of the discourse might seem to some far-fetched, since, superficially, a bar of polished brass or steel apparently presented the archetype of a homogeneous solid Any such idea, however, must in a few moments be dispelled. Taking a section of pure gold, or at any rate of gold of a purity of 99.995 per cent, this, when polished and etched presented under a low power of the microscope large allotrimorphic crystals, the etching figures of which exhibited varying orientation in different crystals Hence (see Fig 1) one crystal might appear black, another show the brilliant yellow of gold and a third exhibit middle tone All these were purely optical effects In the

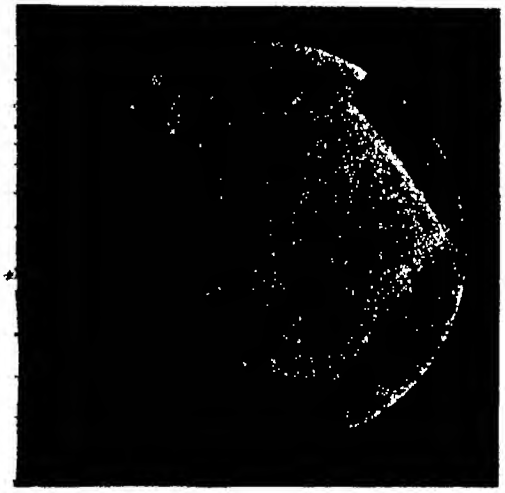

FIG 1—Gold

black crystal the orientation was at such an angle as to reflect the light entirely outside the objective, whilst, going to the other extreme, the gold-coloured crystal had a molecular orientation which reflected the light entirely into the objective It was well known that the addition of one or two tenths per cent of the metal bismuth to gold produced a surprising mass brittleness which naturally led to the enunciation of theories to account for so remarkable a phenomenon

Twelve years ago the theory which commanded a general acceptance, and at that time reasonably so, was that the small quantity of bismuth was incapable *per se* of producing so profound a mechanical change as to convert one of the most ductile of metals into a mass possessing an almost glassy brittleness Therefore, the metal bismuth must act indirectly, its presence determining the maintenance of the molecules of gold in a brittle allotropic modification

In 1896 there was published in *Engineering* from the laboratories of the Sheffield College an unambitious research recording the discovery of eutectic cements which to a considerable extent altered the whole trend of metallurgical thought

[1] Abstract of a discourse delivered at the Royal Institution on Friday, February 23, by Prof J O Arnold

Fig 2 shows a micro-section of the structure of gold to which 0.2 per cent of bismuth had been added The microscope had at once explained the hitherto mysterious action of bismuth It indicated clearly that the small quantity of bismuth alloyed with a definite amount of gold forming a constituent having a much lower freezing point than the main mass Hence, when crystallisation set in during solidification from a series of centres, the "eutectic" or constituent last fluid was expelled to the exterior of each crystalline grain of pure gold, thus enveloping each crystal in a membrane of gold bismuth alloy having a much higher coefficient of contraction than the crystal itself Hence, during cooling, the gold-bismuth alloy, which may be regarded as the mortar of the structure, to a considerable extent detached itself from the crystalline grains of gold which may be regarded as the stones of which the mass is built up In the micrograph Fig 2 the stones of tough gold are represented as white whilst the mortar of gold bismuth eutectic is shown as dark thick enveloping membranes These membranes become pasty well below a red heat and it was proved that at 400° C the mass could be powdered in a mortar the crystalline grains of pure gold becoming detached from the feeble alloy cementing them together One of these crystalline grains exhibited no signs of the brittleness of the mass from which it was thus detached but was readily beaten out into gold leaf in the ordinary manner

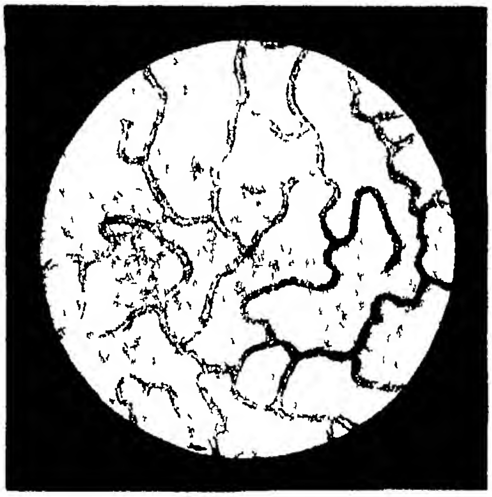

FIG 2—Gold containing 0.2 per cent of bismuth

Passing from gold to brass it was proposed to diverge from the abstract to the concrete and to show the value of the application of the science of metallurgy to practical problems connected with mysterious failures in marine engineering

A notable case in point was the explosion of the brazed copper main steam-pipe of the s s *Prodano* in calm weather off the Kentish Knock at a pressure about one tenth of that to which it had been previously tested In this case the microscope was again successful in clearly indicating the nature of the electrolytic decay, under certain conditions of brass used in naval architecture In this connection a familiar phenomenon is the decay of Muntz metal bolts exposed to the action of bilge water Such bolts break suddenly and present a distinctly coppery fracture A micrographic examination of such bolts usually revealed a minor area of undeteriorated brass and a major area of deteriorated brass—that was to say brass which had been more or less dezincified, an expression which meant in other words that the mass had become transformed into rotten, spongy copper

Brass often consisted of two constituents namely a ground mass of true brass of formula Cu_2Zn and a eutectic corresponding to the formula $Zn\,Cu$ Upon a mass so constituted a feeble saline electrolyte attacked in

the first instance the constituent rich in zinc, whilst the constituent rich in copper assumed an electronegative position, acting, of course, as the kathode of the couple.

But when the eutectic had been transformed into spongy copper, the latter assumed the electronegative position and the true brass became the anode, hence gradually transforming the whole mass from Muntz metal into spongy copper. In the case of the *Prodano*, the electrolyte was proved beyond all doubt to have consisted of fatty acids due to the use of improper lubricants. Little by little the brazed seam was cuprified until the junction became so weakened that at a pressure of only 130 lb. per square inch the port main steam pipe opened for a space of 6 feet and consigned four men to an agonising death.

This research, made at the Sheffield College under instructions from the committee of Lloyd's Register, resulted practically in the abolition of brazed copper main steam-pipes and in the substitution of rolled steel ones.

Reaching the third section of the lecture, this undoubtedly must be regarded in the steel age as the most important, since it dealt with steel. Taking the base of steel, namely, pure iron, this had a similar structure to that of pure gold, but the etching figures exhibiting the molecular orientation in the allotrimorphic crystals of this metal were seldom revealed by ordinary etching.

Broadly speaking, iron was converted into steel by the addition of the element carbon, and researches made in the Sheffield College indicated that steels naturally divided themselves into three classes, namely, unsaturated, saturated, and supersaturated steels. If 0.3 per cent. of carbon were added to steel the carbon converted one third of the iron into the constituent pearlite, and in such a steel as cast the iron or ferrite frequently arranged itself into a pattern indicative of cubic crystallisation exactly comparable with the figures observed by Widmanstatten in the non-terrestrial steels called meteorites. In saturated steels just sufficient carbon approximately 0.9 per cent. had been added to the ferrite to convert it totally into the constituent pearlite, a definite mixture corresponding to the formula $(21Fe+Fe_3C)$. This definite mixture presented at least three well-marked phases having different mechanical properties determined by the state of the division of the carbide Fe_3C. These phases might be differentiated by distinguishing the involved carbide as emulsified, normal, and laminated, the latter being the pearly constituent of Sorby, presenting a play of gorgeous colours determined by the varying thickness of the lamina acting like mother-of-pearl in nature, or the interference grating in science. Through no scientific foresight, but as a matter of fact by an act of carelessness, there had been secured at the Sheffield College a section showing the transformation of pearlite into hardenite in the most perfect manner yet recorded. The two constituents, pearlite and hardenite, might humanly be described as the most important in nature, since upon unhardened and hardened steel depended the remarkable triumphs of the civil, the mechanical, and the electrical engineer.

The quartz-hard transformation product of pearlite discovered by the versatile genius of Dr. Sorby itself presented what might be termed effective and futile phases dependent upon the temperature of quenching. In properly quenched steel the accidental section before referred to showed that at a moderate temperature the transformation proceeded not suddenly, but from a series of converging centres until the whole mass consisted of the obsidian-like substance, structureless hardenite. At too high a temperature this steely obsidian developed decisive cubic crystallisation, recorded in the micro-structure by equilateral etching figures indicative of ruined steel. In supersaturated steel in the unhardened condition the cells of pearlite were environed by brilliant walls of cementite Fe_3C, which in hardened steel enveloped similar cells of hardenite corresponding to the empirical formula Fe_3C.

Of the three broad types of steel described by far the most important was unsaturated steel, a synonymous term for which was structural steel, embracing boiler-plates, ship-plates, bridge-plates, rails, and the gigantic engine parts which formed the backbone of our battleships and cruisers.

To show the enormous importance of the scientific study of this class of steel, it was well to indicate, not only its failure but after brilliant service, also that of the microscope scientifically applied.

The figure thrown upon the screen was that of a boiler, which might be described as several sorts of boiler. It was a marine boiler, a cruiser's boiler, and possibly a mad boiler—it was, at any rate, cracked. Fortunately this rupture occurred before the cruiser was put into commission, and a defect in the steel which might have resulted in a catastrophe was detected by an extra inspection after the boiler had been impressed with the Government pass mark. The chronology of the testing operations was recorded in the following table:—

Date	Nature of pressure	lb. per sq. in.
February 5	Hydraulic	228
,, 8	,,	260
,, 19	,,	305
,, 20	Steam	60
,, 21	Hydraulic	270 (burst)

The mechanical tests of the boiler-plate steel which had thus failed left little to be desired, and the same remark applies to static mechanical tests taken along the line of fracture. Micrographic tests indicated that the steel presented marked features of inferiority when compared with undoubtedly good boiler-plate steel. Superficially the matter was thus solved, but, under alternating or dynamic stress tests slightly beyond the elastic limit, the steel registered tests varying from 230 to 1292 alternations. The most disconcerting feature in these astoundingly divergent tests was that the test bars registering them were identical in micrographic structure.

At the Cambridge meeting of the British Association the lecturer suggested that these divergent tests must be associated with opposite sides of the plate subjected to varying heat treatment. The lecturer was quite wrong, and after twenty-five years' experience had failed to realise the fact that in connection with steel one must often expect the unexpected.

Remarkable failures in structural steel were commonly associated with the phenomenon called "fatigue." What was "fatigue"? Some little time ago, in an important naval trial at the King's Bench, counsel requested the lecturer to define for My Lord the meaning of this term, which had frequently occurred during the trial, and which he failed to understand. Unfortunately the lecturer also was involved in the outer darkness of My Lord on this matter, but was compelled to give "fatigue" at that time a definition which remains substantially true to-day, namely, that he regarded "fatigue" as a generic term used clearly to explain all cases of fracture which were not understood. Before venturing to suggest an explanation for these mysterious fractures for which popular blame often fell upon men who were doing their very best, he would ask his hearers to imagine that that small cloud no bigger than a man's hand, now hovering over the North Sea, should burst in storm, and that our armour, our guns, and our armour-piercing shells should be put to the stern implacable test of actual warfare. Supposing our guns were faulty, our shells failed to penetrate the armour of the enemy, our armour was incapable of protecting the gallant inmates of our battleships, assuming this hypothesis, which the lecturer believed to be totally untrue, what would all this mean? It would mean that the internal architecture of British wrought steel was all wrong, and the interesting question thus arose, who were the men responsible for the internal architecture of these metals? The lecturer knew them well. They were grave-eyed men with set mouths, who week after week, month after month, and year after year lived and moved, and had their being, and sometimes died, amid the flare of gigantic furnaces and the rattle of Titanic rolls, steadfastly working upon those metals which formed Britain's first line of defence, and to-night on behalf of these inarticulate men the lecturer confidently asked his distinguished audience to exclaim in their hearts, "These men have deserved well of their country."

Reverting to the remarkable and disconcerting fact that two pieces of the faulty boiler-plate steel of identical structure, so far as could be seen by the microscope, gave astoundingly different results under dynamic stresses, the

lecturer put forward as a tentative hypothesis the theory that, underlying the gross and visible micro-structure of the steel, there existed a molecular structure, which in the present state of knowledge could not be detected, except in rare cases, by the microscope. It was suggested that this molecular structure was brought about by improper heat treatment developing in the ferrite from a series of centres well developed mineral cleavage. On the circumference of these centres existed areas in which the molecular cleavage was less perfectly developed, and beyond these were the areas of good steel in which the cleavage lines were extremely imperfect. It was then easy to conceive that the plane of dynamic fracture in a perfectly developed cleavage area might give the remarkably low record of having endured only 230 alternations as in the table previously exhibited on the screen, whilst a test-piece in which the plane of fracture went through an area of good steel free from what might be called cleavage disease might readily endure 1200 alternations before breaking, and a third test-piece from the middle zone of somewhat developed cleavage might endure, say, 700 alternations. This theory, at any rate, was in accordance with the mechanical facts which had been presented. Another step towards the experimental verification of this hypothesis would be to prove that iron was a veritable mineral as capable of exhibiting geometrical cleavage as was, say, fluor-spar or Carrara marble. Fortunately the lecturer

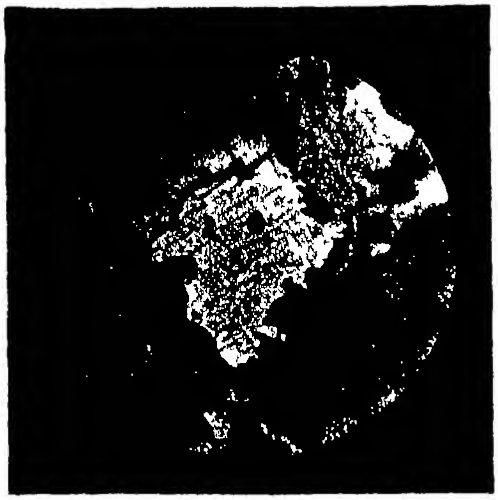

FIG. 3.

found himself in a position, by what might be called a million-to-one chance, clearly to prove that iron could possess absolutely perfect mineral cleavage parallel to the faces of the cube. This discovery came in no heroic form from the swift-moving machinery of a destroyer or in connection with metal forming the stupendous engines of a battleship, but in connection with a wrought-iron bolt literally forming part of a common or garden gate-post. This fractured under the taps of a hand-hammer during repairs, and one of the crystals cleaved exactly at right angles to the axis of the bolt, and consequently when the fractured end was cut off in the lathe for examination it was found at right angles to the axis of the microscope, exhibiting the wonderfully perfect cubic cleavage delineated in Fig. 3.

Metallurgists had now arrived at a deadlock. The microscope, after rendering great services, had in its turn broken down, mainly owing to the fact that optical examinations associated with transmitted light could not be applied to opaque objects, and in more senses than one the scientific metallurgist could not yet see through steel. Nevertheless, he must endeavour to tear down this mysterious veil or in some way get behind it, and in the lecturer's opinion the resources of science in connection with steel metallurgy were not yet exhausted.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. A. C. SEWARD, F.R.S., has been appointed professor of botany in the University of Cambridge in succession to the late Prof. Marshall Ward.

WE learn from *Science* that Mr. J. A. Creighton, one of the founders of Creighton University, Omaha, Nebr., has presented to that institution two buildings worth about 100,000*l*.

AN interesting educational development in Manchester is recorded in the *Electrician*. The Corporation of that city has just decided to take approved students from the School of Technology into the electricity works for a three years' training, giving them a certain small but increasing salary during that time. This privilege is to be restricted to sons of Manchester ratepayers.

IT is announced in *Science* that Mr. A. C. Chapin has given Williams College an additional gift of 10,000*l*. to be used by the trustees without restriction, and that Mr. C. T. Barney has given 2000*l*. to the college. It is stated that the fund for Oberlin College, as completed, amounts to 100,300*l*. This includes the following funds:—25,000*l*. for a new library building given by Mr. Andrew Carnegie, 20,000*l*. for library endowment, 20,000*l*. from an anonymous donor in Boston for the increase of salaries of teachers in the college and seminary, and 30,000*l*. for miscellaneous purposes. The gift of the Boston donor enables the trustees to increase by 40*l*. the salaries of twenty-four full professors.

THE following announcement appears in the volume of Regulations (Cd. 3201) just issued by the Board of Education containing the prospectus of the Royal College of Science, London, with which is incorporated the Royal School of Mines (session 1906–7):—"It is probable that as a result of the investigation made by the departmental committee lately appointed by the President of the Board of Education various changes will be made in the organisation and relations of the Royal College of Science, including the Royal School of Mines. The Board therefore give notice that the arrangements detailed in this prospectus are subject to such alterations as they may determine in respect of the classes for the college session 1906–7 and of courses of study in future."

THE last report of the Scotch Education Department dealing with secondary education in Scotland directs attention to a new departure in the method of awarding leaving and intermediate certificates. The report states that last year the aid of the teacher was actively enlisted in determining the question of success or failure, and that much weight was attached to a pupil's school record, as properly attested by his teacher, in the allocation of school bursaries. The secretary puts it on record that events have completely justified the confidence of the Department. The teachers, as a body, have risen to the responsibility that was placed upon them. Of course there were cases of miscalculation by the teacher, but these were rare exceptions. The success which this Scottish experiment has met in the direction of humanising the methods of appraising knowledge and intellectual training, with the object of selecting the best pupils, should encourage those responsible for examinations south of the Tweed to increase their efforts to abolish the mechanical character of many of the current tests to which young students are subjected.

THE annual general meeting of the Association of Teachers in Technical Institutes was held on Saturday, October 27. Mr. W. J. Lineham, president, occupied the chair, and Mr. V. Mundella was elected president for the ensuing year. The following resolutions were adopted:—(1) That the association urges the desirability of attendance at evening continuation schools between the ages of fourteen and sixteen being made compulsory upon all not in attendance at elementary or secondary schools. (2) That in view of the generally inadequate provision made in the present scholarship schemes of local educational authorities for the needs of scientific technological and trade students, the local branches of the association be instructed to consider what amendments of local scholarship schemes

are necessary to meet the needs of such students, and to press such amendments upon the local education authority with the view of remedying the defects indicated (3) That the attention of the technological branch of the Board of Education be directed to the desirability of recruiting the staff of inspectors from those with experience in technological teaching

By the will of the late Mr John Daglish, Armstrong College, University of Durham, will eventually receive about 45 000*l* After the payment of claims on the estate and certain legacies, the whole of the testator's property is placed in the hands of trustees upon trust to pay the income to the testator's widow during her life Subsequently 5000*l* is to be paid to Armstrong College for the foundation and maintenance of a travelling fellowship in mining and the associated subjects to be called the 'Daglish Fellowship' As certain annuities successively fall in, the income is to be paid to Armstrong College for its general purposes, among which three, in the order named are to have precedence The first of these is the augmentation of the principal's stipend to 1500*l* a year, the second is the augmentation of the stipend of the professor of mining to 800*l* a year, and the third the augmentation of the stipend of the professor of agriculture to a similar sum When all the annuities have fallen in, the trustees are to hand over 30,000*l* to the college to be invested for its general purposes The income of the residue is to be paid to Armstrong College, to be applied as ordinary revenue, until the council of the college shall erect as one scheme further buildings costing not less than 20 000*l*, and shall have received from legacies or subscriptions 10 000*l* applicable to such buildings

THE new buildings of the King Edward VII Grammar School at King's Lynn presented by Mr (now Sir) W J Lancaster, were opened by the King and Queen on Monday The Town Council of Lynn provided the site for the buildings which with the foundations cost more than 43,000*l*, and include chemical and physical laboratories and lecture-rooms In the reply of the King to an address of welcome presented by the Mayor of Lynn, the words occur —"The occasion of our presence here to-day shows that you are not content with the traditions of the past however worthy of remembrance those may be, but through the liberality of an old pupil of the school which bears my name the new buildings of which I am now about to open, are determined to keep abreast of the times and are conscious that it is only by a thorough education that the younger generation can hope to prove successful in later life" An address was also presented by the governors of the school and the King read a reply in the course of which he said —"You are aware of the deep interest which I have always taken in the public institutions of the county of Norfolk and in all schools established for the purpose of imparting higher education It is not easy to over-estimate the far-reaching benefits of the tuition obtained in such an institution as this You, as governors of the school will, I feel sure exercise the most solicitous care in the direction of the studies of your pupils that they may be able to face the stress of life with an intellectual equipment such as will enable them to hold their own in the world and bear their part in its work and duties with efficiency and to the benefit of others nor will I feel confident, the higher teaching of morality, truth, and self-respect be neglected"

THE annual report of the council of the City and Guilds of London Institute for 1906 has reached us In the last report the council directed attention to the financial position in which the institute had been placed by the reduction of the contributions of the Corporation and the Mercers' and Fishmongers' Companies, but in the present report the council is able to state that the Corporation has reverted to its previous contribution of 500*l* —the amount in 1904 having been reduced to 400*l* —and has decided to contribute a similar sum for each of the following five years The Mercers' Company has also reverted to its original contribution of 2000*l* The Vintners' Company has increased its contribution, and the Saddlers' Company has withdrawn conditions previously attached to its subsidy The Fishmongers' Company has yet to rescind its resolution to reduce its contribution from 4000*l* to 2000*l*. The extracts printed in the volume from the examiner's reports should be carefully read by teachers and students Apart from the value of the suggestions and criticisms they contain, they afford an instructive insight into the mental capacity of the artisans, who are training to become skilled operatives in many of the chief branches of industry They show very clearly where the preliminary education of these students is at fault, and the errors into which they most frequently fall The council remarks that from the reports furnished by the examiners it appears that, on the whole, there is a gradual but distinct improvement in the character of the students' work, and in the knowledge, intelligence, and skill which their answers and exercises display

AN address by Prof George H Mead, delivered before the Chicago Chapter Sigma Chi in March last, is reprinted in *Science* for September 28 Prof Mead states that science in the colleges of Chicago and other American universities has not the importance and popularity that it should have This is due, it is said, to the freedom of choice of studies in the preparatory schools, the scientific courses are not selected by the children at a period when the concrete subject-matter of science properly presented should be immensely more attractive than languages and abstract studies The science courses in the high school are not Prof Mead affirms, popular at the present time, nor is the money spent on them, whether in equipment or teaching staff comparable with their educational importance The result is that the majority of American students leave the universities without a grasp of the important achievements in modern thought, and without being able to interpret what they see hear and feel, by means of the splendid generalisations now known to the world Prof Mead explains the unpopularity of science in schools and colleges by the statement that scientific problems are no longer within the immediate experience of the student, and not always to be expressed in terms of that experience In addition, he says, the natural sciences are not inter-connected in the minds of the students Discussing the remedy for this misfortune, Prof Mead thinks it lies with the schools where children should be introduced to science in an intelligent manner Until this is done the colleges he maintains, should arrange introductory courses in science, in which the subject should be presented from the points of view of history and of a survey of the world of science as a whole In this way, the address contends the culture value of science would become clear and suitably esteemed

A RECENT article by Mr J L Bashford in the *Westminster Gazette* provides an interesting description of the Berlin High School of Trade, or Merchants' College, which was opened in the presence of the Crown Prince a few days ago The college has been erected by the Corporation of the Merchants of Berlin at a cost of about 166 000*l* and will be maintained entirely by the same body The State has in this instance made no grant nor did the idea of the college originate with the Education Department This Berlin school is the only institution of the kind in Germany, and is intended for merchants The aim of the teachers will be to give the students knowledge and a theoretical training Lectures will be delivered on all subjects connected with the usances of trade—exchange, banking, Stock Exchange, gold and silver standard, investment of capital, the history and technique of certain branches of industry—*e g* electricity, machines and the textile industry, book-keeping, arithmetic and insurance, trade politics, political economy, statistics social questions, the requirements of workmen in factories, the money market and its organisation in Germany, England France, and the United States of America, civil law, commercial law, and every other form of law connected with trade relations, commercial geography and commercial history Philosophical and art studies also find a place in the programme, and knowledge of foreign languages as well as knowledge of foreign countries The new college contains an aula, capable of holding about 600 persons, and nine lecture-rooms, some for forty and others for fifty 100, and 150 students, as well as a laboratory for chemistry and one for physics

FROM Continental contemporaries we note the following recent appointments:—Prof. H. Rubens, professor of physics at the Technical High School, Berlin, to be professor of physics at the University of Berlin and director of the Physical Institute; Prof. Arthur Wehnelt, professor of theoretical and applied physics of the University of Erlangen, to be a professor and departmental director in the University of Berlin; Dr. Joseph Grunwald, privatdocent at the University and the Technical High School of Vienna, to be extraordinary professor of mathematics in the University of Prague; Dr. H. Mache, privatdocent of the Vienna University, to be extraordinary professor of physics in the University of Innsbruck; Prof. Cæsar Pomeranz, extraordinary professor of chemistry in the Vienna University, to be professor of chemistry in the University of Czernowitz; Prof. Karl Zsigmondy, professor of mathematics in the Technical High School, Prague, to the chair of mathematics in the Technical High School, Vienna; Prof. Reissner, privatdocent in the Technical High School, Berlin, to be professor of mechanics in the Technical High School, Aachen; Prof. Zdenko Skraup, professor of chemistry in the University of Graz, to the chair of chemistry in the University of Vienna; Prof. Franz Streintz, privatdocent of the University of Graz, to be professor of physics of the Technical High School in Graz.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 31.—"The Viscosity of the Blood." By Dr. A. du Pré **Denning** and John H. **Watson**. Communicated by Prof. F. Gotch, F.R.S.

It is urged that the full import of a knowledge of the variations in the viscous resistance to be overcome by the blood in circulating through the capillaries and smaller vessels of the system, and the significance of such data to the more exact consideration of a large number of normal and pathological conditions, especially those of the circulatory system, have not been fully realised by either clinicians or physiologists. Experiments have been undertaken to observe the influence of the number of the corpuscles present upon the viscosity of the blood under varying conditions of pressure and temperature, the rate of flow through capillaries of different sizes under the same conditions, and the alterations caused by the additions of certain salts and other substances; one important result of the experiments was to show that the decrease in viscosity for each degree rise of temperature for a blood rich in corpuscles is considerably greater than for a blood poor in corpuscles, especially when the flow is through the finer capillaries, or, in other words, the flow of blood does not follow the fourth power of the radius as required by the Poiseuille formula. An attempt is made to indicate briefly the import of the results obtained in a consideration of the mechanism of the circulatory system. At the end of the paper an account is given of a clinical viscosimeter which the authors have devised for determinations of blood viscosities with but a few drops of blood, such viscosity determinations, it is claimed, are necessary supplements to hæmacytometer observations.

June 21.—"On the Behaviour of Certain Substances at their Critical Temperatures." By Dr. Morris W. **Travers**, F.R.S., and Francis L. **Usher**.

Traube, de Heen, and others have recently suggested that the simple theories of Andrews and Van der Waals may be insufficient to account for the changes which take place in pure substances at their critical temperatures. Their evidence appears to show that in the case of such substances as ethyl alcohol and ether the Cagniard Latour temperature is dependent on the relative volumes of the two phases, and to account for this they have suggested the existence in the system of complex molecules.

The authors have carried out investigations with ether and with sulphur dioxide, and have found that the Cagniard-Latour temperature is independent of the conditions under which the experiments are carried out. Particular precautions were taken to obtain the liquids pure and to maintain steady temperatures, the measurements of which were certainly accurate to within 0°.05.

The second part of the paper deals with the phenomenon of opalescence which is observed in pure liquids at their critical temperatures. If varying quantities of a pure liquid are heated in sealed glass tubes, provided that the liquid neither disappears nor completely fills the tube before the critical temperature is reached, the surface separating the two phases may sink and disappear near the bottom of the tube, or it may remain stationary about the middle of the tube, or, lastly, it may rise and vanish near the top. In all three cases, if the temperature is raised so slowly that equilibrium is attained without ebullition of the liquid phase, the contents of the tube become opalescent at a temperature slightly below that at which the surface vanishes, the effect being similar to that produced by the action of oxidising agents on a solution of sulphuretted hydrogen. When the surface is falling the opalescence appears in the space below it, and when the surface is rising, in the space above it. In either case the opalescence is confined to the space in which it first appeared by the moving surface, and its intensity is inversely proportional to the volume it occupies. Although it is fairly evenly distributed through the space it occupies, it is usually more intense very near to the surface, and when the latter disappears gradually becomes diffused through the whole tube.

In the case where the surface appears to remain stationary, the tube appears slightly and evenly opalescent throughout its whole length, and if, when this is the case, the volume of the space containing the substance is increased or decreased, opalescence appears below or above the surface itself, and its intensity is inversely proportional to the space it occupies. The effect persists over a finite range of temperature. In the case of sulphur dioxide it sets in at 0°.1 below that at which the surface vanishes, attains a maximum at about 0°.05 above it, and completely disappears at a temperature 0°.1 higher. In the case of ether the effect persists over about 2°.

The conditions necessary for the existence of complexes in a liquid-vapour one-component system in the neighbourhood of the critical temperature were given by Donnan at the British Association in 1904. He suggested that at the critical temperature the interfacial tension becomes zero for ordinary values of the radius of curvature, but remains positive for very small values, for which it does not become zero until the critical temperature is passed. Hence it may be assumed that at temperatures slightly below the critical the interfacial tension is greater for very small radii of curvature than for ordinary curvatures. If over a range of temperature including the critical temperature, limited above by the temperature at which the interfacial tension for very small curvatures becomes zero, and below less sharply, small non-molecular aggregates can be formed, it follows that these will be differentiated from either the liquid or vapour phase, and will have a stable existence. To such aggregates is attributed the phenomenon of opalescence, and the range of temperature over which it is observed, and the manner of its appearance and disappearance, are in agreement with the assumptions.

A CORPUS OF AUSTRALIAN MYTHS.

Mythes et Légendes d'Australie, Études d'Ethnographie et de Sociologie By A van Gennep Pp cxvi + 188 (Paris E Guilmoto, 1906) Price 10 francs

WITH few exceptions the works on Australian aborigines are in English, the older ones are out of print, the newer ones exceedingly technical, demanding on the part of the reader some enthusiasm and a good deal of preliminary knowledge M van Gennep, therefore, has put before the French public a general survey of various controverted questions of Australian ethnography and sociology as a preface to the hundred and six myths and tales translated in the second portion of the volume before us

The eight chapters of the introduction deal with somatology and culture, kinship and descent, the methods by which social modifications are introduced, aboriginal ideas as to conception and reincarnation, exoteric and esoteric doctrines with regard to the bull-roarer, the idea of magico-religious power, the relations of myth and rite, and the content of the myths There are additional notes on the subject of Arunta primitiveness and on reincarnation and totemism

In the somatological section the author emphasises the local differences both as regards indices, pigmentation, and hair character, finally inclining to the views of Spencer and Gillen that a second race with three lines of migration has been superposed on an older stock akin to the Tasmanians M van Gennep then passes on to discuss the various attempts to identify the culture of Australia with that of Palæolithic Europe, and to distinguish various cultural cycles corresponding to ethnical differences, he comes to the conclusion that Schoetensack's theories are not proven, the coincidence of cultural elements being rather due to similarity of conditions The cultural areas of Frobenius and Graebner he dismisses as insufficiently evidenced, and vitiated by neglect of the influence of inter-tribal commerce

The chapter on filiation is complicated by controversies with M Durkheim on the one hand, Mr Andrew Lang on the other, the author holds that modification of the rules of descent is due to the change of view on physiological questions, where the child belongs to the kinship group of the mother, little or no part in producing conception is assigned by the tribe in question to the father, and *vice versâ* It seems a fatal objection to this view that whereas the Arunta are stated to have no idea of the importance of the male parent in this respect, they reckon descent of the intermarrying class through the father How could this come about? Does M van Gennep hold that they originally believed the child to be procreated by the father, and made the class rule fit in with this idea, that they subsequently modified their views on the mechanism of conception, and then adopted a new rule for the totem, retaining the old one for the class? This view seems to land us in considerable difficulties A criticism of the views of M Durkheim in this chapter contains an extraordinary misstatement, the Arunta have no rule that two persons of the same totem may not marry, just as they have no tabu of the totem animal, in reply to M Durkheim's statement of this fact, M van Gennep replies that the exogamic rule is strict among them A more unfortunate lapse it is impossible to imagine Apropos of the Arunta in particular, M van Gennep propounds a theory of the origin of classes in opposition to the commonly accepted dichotomous hypothesis, he holds that they originated " by convergence ", but unfortunately we do not learn what this means, save that it is in some way connected with the binary system of numeration which is almost universal in Australia

A long and important chapter deals with the ideas relative to sexual matters, but space is lacking for an analysis of this and of the chapter on the bull-roarer, the author suggests that the Australian deities associated with the latter are in reality thunder gods, a theory for which there is much to be said His suggestion on the other hand, that all other Australian divinities, so called, are either culture heroes or the body of deified ancestors, to use a somewhat inexact term, which among the Dieri are known as the *mura-mura*, is less acceptable, the only basis for this theory seems to be the fact that the *mura-mura* were originally spoken of by some incorrect writers as a god

On the subject of magico-religious power, or *mana*, M van Gennep holds that we must provisionally take the view that the Australians distinguish three kinds that of the *churinga* of the *arungquiltha*, and of the *atnongara* and it is to be hoped that workers in the field who commonly overlook the wide issues raised by their researches, will not fail to devote especial attention to this problem As a result of his discussion of myth and rite M van Gennep comes to the conclusion that the problem of anteriority is insoluble

The hundred and six myths which follow are carefully annotated and should give the reader a good idea of Australian myths and legendary tales As to the utility of M van Gennep's work there can be no doubt, but if he were writing for an English public the general impression would be that he had better have relegated controversy to a subordinate place and have aimed rather at expounding what is known than at putting together an introduction full of technical matter

THE LIFE AND WORK OF PLANTS

The Physiology of Plants, a Treatise upon the Metabolism and Sources of Energy in Plants By Dr W Pfeffer Second fully revised edition translated and edited by Dr Alfred J Ewart Vol iii Pp viii + 451 (Oxford The Clarendon Press 1906) Price 18s net

THAT Dr Pfeffer's great work has been issued in a worthy English translation is matter of congratulation to those to whom its treasures are thus rendered accessible, while welcomed by those familiar

with its value in its original form, who will find in it valuable additions, interpolated in brackets and in an appendix, which take account of the recent progress of the science

The newly issued third (and last) volume deals with the great subjects of movement, the production of heat, light and electricity, and the sources and transformations of energy in plants As in the former volumes, the width and accuracy of the author's acquaintance with the literature of the subjects under treatment are marvellous, and scarcely less so is the power of arrangement by which it is made available to others The book demands continuous and close attention from its readers, for it is crowded with information condensed so far as it can be without sacrificing clearness Dr Ewart deserves thanks for the excellence of the translation, a task the difficulties of which can be appreciated only by those that have attempted to translate a German scientific work into good English, and have experienced how hard it is to do so He deserves thanks also for wise reticence as regards the introduction of new technical terms, the employment of which is a very real obstacle to the progress of science unless they are required to ensure accuracy Most parts of botany have suffered more or less from this evil, and it is thus all the greater a pleasure to mark its absence from so fundamental a work as this

The treatment of each subject is exhaustive and of much interest While it demands the reader's undivided attention throughout, there is a noteworthy freedom from obscurity in the language, for which thanks are due to both the author and the translator

Under movement, the causes and mechanism are first discussed in preparation for the consideration of the varied kinds of movements in detail These are distinguished into movements of curvature, tropic movements, and locomotory and protoplasmic movements Under the first head are included autonomic movements, the movements of climbers and twiners, those due to mechanical and chemical stimuli, photonastic, thermonastic, and hydronastic curvatures, and the movements connected with dehiscence and dispersal Tropic movements are treated in a general way, and thereafter, under the various forms, the conditions for and the mechanism of each are dealt with The movements of protoplasm and its reactions to stimuli are placed under the third head, whether shown by locomotion of the entire cell or by movements of the protoplasm within the cell wall

The production of heat, light, and electricity by plants is thereafter discussed, and this is followed by a chapter on the sources and transformations of energy in plants, in which it is stated that, "apart from the locomotory movements which are absent from most plants, as many external manifestations of energy are shown in the vegetable kingdom as among animals" How widely different is such a view from that which regarded plants as little more than inert things, possessed of life and able to grow and to reproduce themselves, but far indeed beneath animals in their powers of response to external stimuli

A brief but very valuable appendix summarising the more important literature on the subject published since the completion of the German edition and an excellent index conclude the work

It will be seen from this brief abstract that this volume deals with subjects of extreme interest, in which great progress has been made towards a fuller understanding of plants as living organisms sensitive to influences from without, and adapting themselves to their environments The modern conception of the study of plants has become very much widened and deepened from that which prevailed when that study appeared to content itself with description and classification Yet there is a danger lest even advance may lead to narrowness of view through the impossibility of acquiring a personal knowledge of more than a limited part of the science of botany The disadvantages of too great specialisation are to be dreaded, and the benefits conferred by Dr Pfeffer's "Physiology of Plants" will be felt by systematists and morphologists not less than by physiologists From it they can gain a clear view of the plant as a living organism and can estimate the value of such knowledge in relation to their special fields of study Such a survey will probably bring to light new problems awaiting solution, and will leave the impression that though much has been accomplished deeper problems of life remain unsolved, and that the field of investigation only widens indefinitely To what has been gathered in its field no better guide can be obtained than that under review

STEAM AND HYDRAULIC TURBINES

(1) *Steam Turbines, with an Appendix on Gas Turbines, and the Future of Heat Engines* By Dr A Stodola Translated by Dr Louis C Loewenstein Second edition, enlarged and revised Pp xix+490 (New York D Van Nostrand Co, London Archibald Constable and Co, Ltd, 1906) Price 21s net

(6) *Modern Steam Turbines* Edited by Arthur R Liddell Vol 1 The Schulz Steam Turbine By Max Dietrich Pp 73 (London A Owen and Co and T Fisher Unwin, 1906) Price 5s

(1) THIS is the second edition of Dr Loewenstein's authorised translation of the second edition of Dr Stodola's well-known treatise The first edition of the translation was recently fully reviewed

in these columns. The only change in the present edition is the incorporation of a supplement, prepared by the translator, giving the derivation, step by step, of the difficult formulæ in Dr Stodola's treatise, this supplement will be very acceptable to advanced students in our engineering schools It is a striking proof of the high estimation in which this text-book is held in the English speaking world that a second edition of the translation should so soon have been called for

(2) In their preface Messrs Stevens and Hobart point out that while a number of treatises on the steam turbine has been published, none of them so far has dealt with the subject from the point of view of the purchaser and user, though to them the question of economy, not only in steam consumption, but also in first cost and maintenance, is of the greatest importance In the second chapter the authors discuss the much vexed question of units, they abandon the well-known B Th U, and adopt for their unit, both for heat energy and mechanical energy, the kilowatt hour, or K W H, though expressing an abstract preference for the kilogram calorie as the unit of energy, similarly for the unit of power they have almost exclusively adopted the kilowatt (K W) in preference to the older unit, the horse-power (H P)

Since in dealing with the economy of steam turbines the authors have reduced all the results to kilograms of steam per kilowatt hour output from the dynamo driven by the turbine, it is inevitable that they should discard the older units We do not think, however, that the well-known B Th U will be displaced for many years to come, it is still the unit in which most English-speaking engineers think who have to deal with practical problems connected with the generation of steam, and it has certain practical advantages That some changes in our system of units will come in course of time we have no doubt, and we have equally no doubt that they will be to the advantage of British and American engineers, though we cannot agree with the somewhat far-fetched hypothesis of the authors that "the rapid rate at which Germany and Switzerland are coming to the front as rivals of English-speaking countries in manufacture and commerce" is due to our present system of units

To each of the types of turbines which have so far been successful on a commercial scale (De Laval, Parsons, Curtis, Rateau, &c), and to several others still more or less in an experimental stage, a separate chapter is devoted In each of these chapters the authors follow a definite procedure, they deal with the turbine, which is being considered, under two heads (not always in the same order) —(a) its economy as a machine for the conversion of heat energy into mechanical energy, (b) its design from the point of view of the user In the sections devoted to steam economy, the effect of varying the boiler, or admission, pressure, of varying the vacuum, and of superheating the steam is fully treated with the aid of most elaborate and carefully drawn up tables and curves are plotted from these tables, both at full and half loads, and the thermodynamic losses are analysed, in the portion of each chapter treating of design, the mechanical principles underlying the design of the turbine under discussion are explained with the aid of a number of reproductions of working drawings, unfortunately on such a small scale as often to render it impossible to make out clearly the details

An interesting point brought out by the elaborate analysis the authors have made of numerous published tests of De Laval and Parsons turbines is that while in the former a considerable reduction in the weight of steam per kilowatt hour is produced by increasing the boiler pressure there appears to be but little gain in this respect in the case of the latter when condensing, if the pressure is increased beyond 8 atmospheres, assuming, of course, that the same vacuum is maintained in each case It is only in the case of the De Laval and of the Parsons turbines that the results of sufficiently numerous tests have been published to enable the authors to discuss fully all the factors which make for economy in any given set of conditions, but they have in all cases given all the information which is so far available for each type of turbine

In connection with the Rateau turbine full details are given of the regenerative heat accumulators which have been erected at various works, where the steam working the turbines is the exhaust steam from previously existing reciprocating steam engines In chapter XIII are a series of steam tables, both in metric and in English units, from pressures of ½ lb to 200 lb per square inch, and two other useful tables, one the calorific values of fuel, the other losses in converting the energy of 1 lb of coal into electrical energy Two valuable chapters are XV and XVI, since in these first typical results are given as to steam economy in modern piston engines and then the authors enter into an elaborate analysis of the respective merits of the piston engine and the turbine from the point of view of working expenses They point out that forecasting the future is by no means an easy matter, it is certain, however, that the relative positions of these two types of engines as to economy in steam consumption will depend to a large extent upon the amount to which their special characteristics are developed and utilised, such as the fact that a high vacuum is more beneficial to the turbine than to the piston engine from the point of view of economy, while, as regards superheating, apparently the reverse holds

The next five chapters deal briefly with such problems as the foundations and engine buildings for turbines, and the cost and arrangement of separate condensing plants, all the data collected in regard to each point being grouped into a series of reference tables In chapter XXII, a very lengthy one the authors have brought together in the form of very carefully arranged tables all the published details of some twelve of the largest and most modern steam-turbine plants, and in addition there are some hundred illustrations, the many blank lines in these tables show how difficult it is to obtain information on points of great importance in connection with the planning of such plants

The final chapter is devoted to marine steam tur-

bines, and the authors have certainly succeeded in bringing together in a convenient form for reference a greater mass of information and data than has ever before been published in any one volume, they have almost attempted to be too up-to-date, as shown in the fact that the new giant Cunarder, recently launched on the Clyde, is called throughout *Susitania* instead of *Lusitania* A valuable bibliography and a complete index conclude a volume which must have involved immense labour in the compilation of the masses of figures with which its pages bristle, and in the preparation of the carefully drawn curves which pictorially represent so many of these elaborate tables, it will undoubtedly for many years be one of the standard works of reference on the steam turbine

(3) This work does not treat of the design of turbines, but gives such information in regard to modern water turbines and their installation as will be required by an engineer engaged in preparing plans for a proposed water-power plant In view of the fact that hitherto there have existed so far in hydraulic-power engineering no generally accepted terms, the author explains in an introduction all the terms he uses, gives a careful definition of each, and suggests that the nomenclature he has used might be generally adopted, it would certainly be a great boon to the student if the authors of text-books on turbines would conform to some definite and fixed nomenclature, both in dealing with the theory and also in explaining the mechanical construction of these machines

The first two chapters are devoted to an account of modern turbine practice in Europe and in America, and Mr Thurso is of opinion that not only have there been marked differences in the development of the turbine in the two continents, but that, on the whole, development has proceeded on more scientific lines in Europe, and much greater mechanical skill has been shown by the turbine builders of that continent in turning out highly-finished machines Up to a few years ago the axial-flow machine was the standard type of European builders, but the difficulty of regulating its speed, and the application of the turbine to the generation of electrical energy, which necessitated higher speeds and closer regulation, has led to the almost complete abandonment of this type, and to the adoption of some form of radial-flow turbine, the actual form adopted varying with the head of water available In America, the author points out, development has been on quite different lines, the modern turbine is a descendant of the radial inward-flow, or vortex, turbine of J B Francis, but, since the number of revolutions varies as the square root of the head of water, and since for the same head the revolutions of different machines will vary inversely as their diameter, the tendency has been, owing to the demand for high speed, to reduce the diameter, and thus to reduce the interior space available for the water to turn and escape axially when its work is done It has thus become necessary to turn the water in an axial direction while still in the runner-bucket, that is, to curve gradually the runner-bucket from a radial to an axial direction, giving these latter a very complicated form, and simultaneously with this there has been a tendency to increase the axial dimensions of the bucket entrances.

Up to a low head, say of 40 feet, the author is of opinion that the American turbine has great advantages over all others in common use, but for high heads he considers it is unsuitable, and that it cannot successfully compete with European types, he is also of opinion that the quality of workmanship and of materials used by American turbine builders is distinctly second-class, due no doubt to the existence of abundant water-power in all parts of the country, and to the belief of the average purchaser that water-power costs little or nothing, and that, therefore, any turbine which will run is good enough for his purpose He also considers that the practice of testing turbines in the flume at Holyoke, where the head is only 18 feet, has been prejudicial to development, since a good result on the test-bed by no means ensures a similar result when the machine is set up in the place where it is to work, often under heads far greater than those available at Holyoke

In chapter iii the various types of turbines are classified, and the general properties and characteristics of each class are briefly discussed, then follows the only chapter devoted to the steam turbine, and, in view of the small amount of space devoted to it, the inclusion of this chapter in the book has been clearly a mistake, it would have been much wiser if the author had omitted the steam turbine altogether, and had devoted the space thus set free to enlarging those portions of the book dealing with the accessories of turbines

The remainder of the book deals with modern types of water turbines, their construction, and the various accessories attached to them for the purpose of admitting and exhausting the water, governing their speed, &c and the decided opinion is expressed that, unless there is some definite reason to the contrary, horizontal shafts should always be adopted, a number of illustrations is given of large turbine plants recently erected in America and in Europe, and the essential points in the design of each are clearly set forth

The chapters on the accessories, &c, are especially valuable, as these details are often either neglected in text-books or treated in a very perfunctory fashion, the data given by the author will be found very valuable by all engineers engaged in planning water-power schemes, and they embody the results of wide experience of various classes of turbines, such important points as the difficulties induced by the formation of ice on a large scale and the means to be adopted to cope with them, and the measurement of water for selling power are fully dealt with

A paper by Mr A V Garratt on the elements of design favourable to speed regulation in plants driven by water-power is printed in the form of an appendix, the whole book is thoroughly up to date in its information, the facts and data are well marshalled, and it should be consulted by every engineer who may be called upon to deal with the problem of the utilisation of water-power.

(4) The great increase in the utilisation of water-power in all parts of the world, mainly in connection with the electric transmission of energy, has led to much more attention being devoted to this branch of engineering in all technical colleges, and this has naturally brought about a demand for text-books thoroughly up to date, and suited to modern developments of the industry. Prof. Church has attempted both to supply this need on the part of engineering students, and at the same time to write a book which will be of service to practising engineers; the subject has been treated by him, therefore, both from the theoretical and from the practical standpoint.

After dealing with the general considerations which govern the design of all types of hydraulic motors, one chapter is devoted to the various forms of gravity motors—overshot, breast, and undershot wheels—which have been so largely displaced in modern days by the turbine. Before dealing with turbine design the author shows that there are three theorems which lie at the basis of the theory of turbines and centrifugal pumps; these theorems are, in fact, fundamental principles of mechanics, though the third presupposes the existence of "steady flow"; this third theorem may be expressed as follows:—

"Power of a turbine in steady motion = angular velocity × change of angular momentum experienced by the mass of water flowing per unit of time in its passage through the turbine."

These theorems are illustrated by a series of numerical examples worked out in full.

In chapter iv. impulse wheels are considered, and the Pelton and the Girard impulse wheels are taken as illustrations of this type; in the next chapter the turbine proper or "reaction turbine," is taken up, and as a preliminary to the discussion of the modern turbine the theory of the Barker's mill is deduced; it is then shown that the Fourneyron turbine is a direct descendant of this old and simple form, and the theory of the Fourneyron form is then worked out both when friction is disregarded and when it is taken into account. Prof. Church then classifies turbines under four heads—(1) radial outward-flow, (2) radial inward-flow, (3) axial flow, (4) mixed flow—and deals with each of these classes in detail; he gives descriptions, with excellent illustrations, of well-known makes of each type, and concludes the chapter with the general theory of reaction turbines. The testing and regulating of turbines form the subject-matter of chapter vi., and a description is given of the Holyoke testing flume. The following chapter is devoted to the theory and construction of centrifugal pumps, and the formulæ deduced are illustrated by working out in full numerical examples.

The flow of water over weirs and through pipes and open channels is treated mainly from the point of view of the designer of turbine machinery, and in connection with this portion of the book there is a series of useful diagrams in the appendix for Kutter's coefficient, &c.

The book concludes with a chapter on pressure engines, hydraulic rams, and accumulators, the Worthington water-motor pump and the Brotherhood pressure engine being taken as examples. Prof. Church's book will undoubtedly be a recognised text-book for advanced engineering students.

(5) This book, originally intended to give a popular account of the history, construction, and operation both of water and steam turbines, has been extended in its scope, and the author has dealt with the important problem of blade design in such a way as to make it a text-book useful also to the technical student. After giving a brief history of the evolution of the water turbine, the conditions which must be fulfilled if such machines are to be efficient are fully discussed; then follow several chapters in which recent modern types of both impulse and reaction turbines are described with the help of a series of good illustrations; finally, this half of the book concludes with some details of the best methods of erecting water turbines and controlling them by governors.

In part ii. the steam turbine is taken up, and naturally attention is chiefly devoted to the Parsons, De Laval, and Curtis turbines; as these are practically the three types which have so far been commercially successful, a full description is given of the principles underlying the design and of the methods adopted in manufacturing the various parts of each of these well-known engines, and it is to be hoped that a study of this part of the book may do something to dissipate the extraordinary ignorance and misconception which prevail among men even of fair mechanical knowledge, in regard to the steam turbine and its possibilities. Special chapters are devoted to the application of the turbine to marine purposes, and a clear account is given of the rapid development in this field of work during the last few years both in the Royal Navy and in the merchant service. Turbo-blowers and rotary pumps are discussed in another chapter, and the advantages of these pumps over reciprocating pumps, where vast volumes of air have to be supplied as is the case in connection with the blast-furnace industry, are clearly set forth.

A series of appendices dealing briefly with the mathematical and mechanical principles involved in elementary engineering, with fluid motion, and with the behaviour of gas, conclude a book which will do much, it is probable, to make the layman take a more intelligent interest in this the latest and most striking development of the skill of the mechanical engineer.

(6) This is an authorised translation of a book by Herr Dietrich, in which he describes the various patents for steam turbines and their accessories taken out by Mr. R. Schulz, engine-works manager of the Germania Shipyard at Kiel, and also the results of tests of the Schulz turbine, both when used for marine work and for the generation of electrical energy.

The rest of the book is devoted to *ex parte* statements in reference to the controversy between Mr. Parsons and Mr. Schulz in regard to their respective inventions, which was eventually fought out in the Law Courts in an action brought for infringement of

patent rights It is not our province to enter into the details of this controversy, we need only say that Mr Schulz claims that he has succeeded better than any other inventor in solving the difficult problem of designing a practical and not too complicated turbine in which the steam consumption per horse-power hour is economical, not only at full power, but also when the engine is working at low loads, and he also claims that he has simplified the arrangements necessary on board ship, where go-astern machines must be provided as well as the go-ahead turbines The author gives a clear description of the mechanical details by which the inventor has secured the results he claims This book should be carefully studied by all those interested in the history of the development of the steam turbine T H B

OUR BOOK SHELF

Ueber chitinöse Fortbewegungs-Apparate einiger (insbesondere fussloser) Insektenlarven By Dr Wilhelm Leisewitz Pp iv+143, with 46 illustrations in the text (Munich C Reinhardt, 1906) Price 4 marks

THE author commenced his observations with the terminal appendage in the larva of *Xiphydria dromedarius* This larva which is almost apterous, lives in galleries in rotten wood, and the appendage is used firstly as a prop and partly to compress the loose substance behind it to give it a firm support as it gradually progresses by gnawing away the wood in front He then extended his researches to the hairs, bristles, &c, of other internal-feeding larvæ, especially those which are apterous or subapterous, and in this small volume we have the results of his careful investigations

The chitinous appendages used for locomotion by such larvæ consist chiefly of (1) undifferentiated hairs, (2) spines, (3) warts, and (4) bristles Where the larvæ live in hard substances, like wood or bark, the appendages consist of short, stiff hairs or spines and warts, but when the larvæ live in soft substances like rotten wood or mould they are provided with long, slender hairs or bristles of varying form

The greater portion of the essay is devoted to larvæ of Coleoptera, though a few others belonging to the orders Neuroptera, Lepidoptera, Diptera, and Hymenoptera are also noticed

Apart from the physiological interest of the inquiry, it is also of some importance to the systematist, for the author claims to have discovered trustworthy characters in the chitinous appendages, which will allow many species of Coleoptera, hitherto supposed to be indeterminable in the larval state, to be easily recognised W F KIRBY

Map of the British Isles Constructed by W and A K Johnston Size 72 inches x 63 inches Mounted on cloth with rollers and varnished (London W and A K Johnston, 1906) Price 21s

THE teaching of geography has received much attention in recent years, and the increased importance given to the subjects in schools has led to the production of several new series of excellent wall maps The present map is a new addition to one of these series It is boldly printed and coloured in a manner to make it easily visible in all parts of a large classroom The scale is 1 633,600, or ten miles to an inch The populations of the different towns are indicated by means of symbols, but it is to be feared that these will be of little use to anybody but the teacher The map will require to be supplemented by an orographical one if the physical geography of our country is to be studied satisfactorily

LETTER TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Production of Radium from Actinium

THE experimental evidence on the growth of radium from uranium has in the past been somewhat conflicting Both Mr Soddy and Mr Whetham have stated that they observed an increase with the time in the amount of radium in solutions of certain uranium salts which were under examination The writer, however, was able to show that, starting with a solution of uranium nitrate carefully purified by repeated crystallisation, the amount of radium formed in an interval of eighteen months was less than one two-thousandth of the amount which was to be expected from the disintegration theory

I think that this discrepancy is readily explained by the results of an experiment which I have just made on the growth of radium from actinium A kilogram of carnotite ore containing about 20 per cent of uranium was decomposed with an excess of dilute hydrochloric acid, and the solution thus obtained was treated with hydrogen sulphide, the precipitated sulphides being subsequently removed by filtration To the solution was then added a fraction of a gram of thorium nitrate followed by a solution of several grams of oxalic acid After standing for several days the slight precipitate which formed was completely removed and converted into a soluble nitrate The nitrate in dilute solution was again treated with an excess of oxalic acid, and this second precipitate was converted into a soluble chloride I have found from a considerable number of experiments that practically all the actinium contained in a uranium mineral can be separated in this manner

The solution of the chlorides containing the actinium was sealed up in a glass bulb, and about two months later, on April 25 last the gases and emanation were boiled out and collected After standing for some minutes the gas was introduced into an electroscope The activity of the emanation corresponded to a content of 5.7×10^{-9} gram of radium in the actinium solution The bulb was again sealed, and was allowed to remain undisturbed until to-day when the radium emanation present was again removed and tested The amount of radium emanation now found corresponds to 14.2×10^{-9} gram of radium, indicating that there has been formed in the solution during this interval of 195 days a quantity of radium equal to 8.5×10^{-9} gram This is equivalent to the production of about 1.6×10^{-8} gram of radium in one year and since the amount of radium in equilibrium with 200 grams of uranium is 7.6×10^{-5} gram, the value of $\lambda(\text{year})^{-1}$ for radium can be calculated, and is given as 2.2×10^{-4} The indicated half-value period would be about 3100 years This number can only be regarded as approximate at present, since the original content of uranium in the material used, and the completeness of the separation of the actinium, are both uncertain I think, however that another step has been made towards the solution of the somewhat complex problem of the genesis of radium, and, since the amount of actinium in a mineral is apparently always proportional to the amounts of uranium and radium present, that actinium will prove to be the looked-for intermediate product BERTRAM B BOLTWOOD

Sloane Laboratory of Yale College, New Haven, Conn November 5

A MODERN PHYSICAL LABORATORY

IN December of last year were opened at Gottingen a number of fine new buildings to accommodate the different subdivisions of the physical department of the University An account of these has just been published in a volume issued under the auspices of the Gottingen Association for the Promotion of Applied Physics and Mathematics[1] This book, a handsome quarto of 200 pages containing numerous illustrations and plans, gives a graphic idea of the elaboration which is now considered necessary for the successful carrying out of work in the different branches of this most rapidly developing science

FIG 1 —North Side of the Physical Institute University of Göttingen

Many physicists can remember the time when, even in the most progressive of our universities where large and well-fitted chemical laboratories had long been established the accommodation accorded to experimental physics consisted of two or three very ordinary rooms, with perhaps a stone pillar or two for galvanometers or cathetometer and a wide shelf outside the window for the Grove or Bunsen batteries By and by came a few accumulators, possibly home-made from jam-pots and roofing lead, the charging arrangements for these consisting of a dynamo of perhaps 25 per cent efficiency and a gas engine, the obstinacy of which in starting on a winter's morning still calls up recollections A pressure of 100 volts was to be treated with great respect, and no laboratory resistance-coil was made to carry more than a few amperes Nowadays it is impossible satisfactorily to house the various subdivisions of experimental physics in a single building, however palatial, and at Gottingen five separate and distinct "institutes" have been provided

1 "Die physikalischen Institute der Universität Göttingen Festschrift, 1906 Pp. iv+200. (Leipzig and Berlin B G Teubner 1906)

The speeches at the opening ceremony of the directors of each of these institutes sketch in an interesting and eloquent fashion the evolution of the whole from its small beginnings and review in succession the many honourable names which, from Gauss and Weber down to our own times, have been associated with the progress of physics at Gottingen Prof Riecke, speaking as head of the parent laboratory of pure physics, mentions how rapid was the increase, during the closing fifteen years of last century of work on the borderland between physics and chemistry, of the type in which Ostwald and Victor Meyer were pioneers This led to the foundation of a separate physical-chemical institute under the direction of Prof Nernst Again, the expansion of applied physics and of electrotechnics, particularly in its developments for lighting and power purposes, was so rapid that in 1898, with the aid of the Gottingen Association for the Promotion of Applied Physics and Mathematics an annexe to the main physics laboratory was erected This developed later with the help of substantial Government grants into the present institute for applied electricity, and when the new physical laboratory was erected the old building was constituted the institute for applied mathematics and mechanics

FIG 2 —Seismological Station, University of Gottingen

A similar evolution from earlier beginnings has been the history of the department for geophysics the child of the observatory for the study of terrestrial magnetism founded by Gauss In a historical *résumé* by Prof Wiechert is quoted a very interesting letter of Gauss to Olbers in 1833 in which he

describes his early experiments in telegraphy over a distance of a mile and a half. The equipment of the seismographic department of the geophysical institute is in every way unique and the new earthquake house built by Prof. Wiechert in 1902 is probably one of the finest in the world.

It is beyond the scope of this article to go into detail on each of these developments, but a study of the volume shows that the facilities provided for the student at Göttingen appear to be fairly comparable in a general way with those now available at Manchester, where the splendid new laboratories of Prof. Schuster at the University, and of the College of Technology in the city, provide together all that could be desired for a complete course of training and research in almost any branch of either the pure or applied science. Though there is much at each of the two universities which cannot be compared to any similar thing at the other, yet many details make the resemblance between the equipments for pure physics distinctly striking; for example, each possesses a large concave Rowland grating, with mounting specially designed for accurate photographic work, made by Krupp and by Sir Howard Grubb respectively. The magnificent equipment at Manchester has already rendered excellent service in the hands of Mr. Duffield in his investigation of the effect of pressure on arc spectra.

The volume under review is well got up and though considerable space is taken up with purely descriptive detail, there is much matter in it of real interest, for example many passages in the speeches delivered at the opening ceremony sparkle in a manner not usual in such efforts. We conclude with a translation of some extracts from the address of Prof. Voigt. He says:—

"What is it then which fetters the crystallographer so strongly to his science? I will try to explain it by a parable.

"Let us imagine in a large hall a couple of hundred brilliant violin-players who all play the same piece with instruments faultlessly tuned, but commence simultaneously at all sorts of different places and perhaps at the conclusion begin over again. The effect is (at least for Europeans) not exactly pleasant: a monotonous jumble of sounds, in which even the finest ear is unable to recognise what is being played.

"Such music the molecules of gaseous, liquid and *ordinary solid bodies make for us*. They may be highly gifted molecules with marvellous internal architecture, but in their activity each disturbs the others. A *crystal* on the contrary corresponds to the orchestra above described when the same is led by a vigorous conductor when all eyes intently watch his nod and all hands follow the exact beat. ... This picture renders it understandable how crystals can exhibit whole ranges of phenomena which are absolutely lacking in other bodies. ... In my opinion the music of physical law sounds forth in no other department in such full and rich accord as in crystal physics."

J. A. HARKER.

THE ETIOLOGY OF SLEEPING SICKNESS.[1]

AMONG the scientific achievements of the last decade few have been so remarkable as the rapid increase of knowledge with regard to the minute animalcules termed by zoologists Protozoa. More especially is this true as concerns the parasitic members of the group and their relation to disease in man and beast. It is now known that protozoan parasites are the cause of many diseases, especially in the tropics, and as a type of such we may refer to malaria, since the etiology of this disease is now so thoroughly known that it may serve as a model, as it were, of diseases due to Protozoa, and at the same time furnishes valuable analogies and suggests the problems to be investigated in other cases.

The classical researches of Laveran, Ross, and others have resulted in establishing clearly the cause and nature of malaria, and have proved definitely (1) that the illness is due to a minute protozoan parasite present in the blood and multiplying there, (2) that the disease is transmitted from sick to healthy persons by certain biting gnats or mosquitoes, a mosquito which has sucked blood from an infected person being capable, after a certain period of time, of inoculating other persons with the malarial parasite at subsequent feeds, and (3) that the parasite is not carried merely passively by the mosquito, but passes through an essential part of its life-cycle within it, since sexual forms of the parasite are developed which conjugate and multiply in the digestive tract of the mosquito in a manner different from the mode of multiplication in the blood of the patient. It is not extraordinary that diseases of this type should be especially prevalent in the tropics, where insect life is so richly developed, and the numerous blood-sucking insects of all kinds furnish the requisite means of transmitting and disseminating the parasitic micro-organisms.

Since Livingstone's time it has been known that horses and cattle in Africa die from a disease produced by the bites of the indigenous tsetse-flies. These flies, of which eight species are now known, belong to the genus Glossina, a genus of Diptera or two-winged flies characteristic of the African fauna and not found on other continents. The disease which they produce, termed nagana or tsetse-fly disease, is rapidly fatal to imported cattle or horses, but does not affect human beings. Various suppositions were put forward as to the nature of the malign power exerted by the dreaded tsetse-fly until the discoveries of Bruce solved the problem once and for all. Bruce found that the disease is caused by the presence in the blood of a minute flagellated organism belonging to the genus of parasitic Protozoa already known to zoologists by the name Trypanosoma, and that the parasite is transmitted from sick to healthy animals by the bite of the tsetse-fly, which was thus shown to play a part in the dissemination of nagana analogous to that played by the mosquito in the dissemination of malaria. Bruce's researches established for nagana the first two propositions stated above for malaria, but it remained to be proved whether the parasite did or did not undergo a definite developmental cycle in the tsetse-fly as the parasite of malaria does in the mosquito. Bruce discovered, however, another fact of great importance, namely, that the "trypanosomes" of nagana are to be found in the blood of indigenous wild game, such as antelopes and buffaloes, to which the parasites appear to be innocuous. These infected wild animals serve, however, as a reservoir for the disease, the trypanosomes being conveyed by the tsetse-fly from the indigenous wild animals to the susceptible domestic animals. No such natural "reservoir" has been proved as yet for the malarial parasite, though its existence has often been suspected.

It had long been known that negroes from the west coast of Africa were liable to a slow but fatal disease, which, from the peculiar comatose symptoms seen in the final stages, was termed the sleeping sickness. Nothing was known as to the nature of this

[1] "*Glossina palpalis* in its Relation to *Trypanosoma gambiense* and other Trypanosomes (Preliminary Report)." By E. A. Minchin, A. C. H. Gray and the late F. M. G. Tulloch. With 3 plates, 1 map and 11 text figures. (Proc. Roy. Soc., 1906.)

mysterious malady until quite recently, when it made its appearance in epidemic form in Uganda, producing an enormous mortality among the natives, and also attacking Europeans The outbreak of the disease was so serious and threatening that, at the request of the Government, the Royal Society sent out a commission to investigate the nature of the disease, and to discover, if possible, the means of checking the further spread of the epidemic The commission was not long in obtaining important results It was discovered that the cause of the disease was a trypanosome which in the early stages of the malady was present in the blood of the patient, but which later penetrated into the cerebro-spinal fluid, and then gave rise to the comatose symptoms characteristic of the disease It was further proved, once again by Bruce, that the parasite was transmitted from sick to healthy persons by the local species of tsetse-fly, *Glossina palpalis*, and that the sleeping sickness was, in fact, a human tsetse-fly disease comparable to the nagana of cattle, though caused by a different species of trypanosome transmitted by a different species of tsetse-fly and differing further from nagana in the nature of the symptoms produced It remained to investigate the exact relation of the parasite to the fly, that is to say, whether the trypanosome went through a developmental cycle in the tsetse-fly or not It may be added that in the case of sleeping

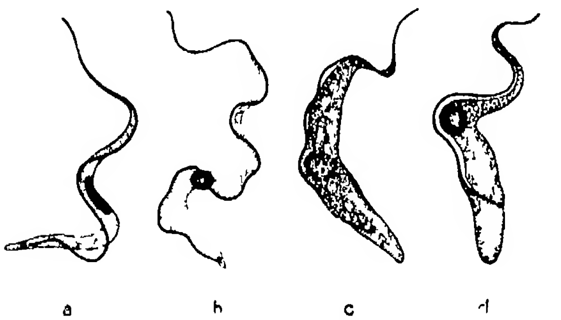

FIG 1 —*Trypanosoma gambiense* from the intestine of the tsetse fly twenty four hours after feeding upon an infected subject *a* and *b* male forms *c* and *d* female forms × 2000 diameters

sickness no natural "reservoir" has yet been discovered

Early in 1905 the present writer was sent out to Entebbe by the Royal Society in order to investigate the exact nature of the relationship between the trypanosome of sleeping sickness, *T gambiense* Dutton (= *T castellanii*, Kruse), and the tsetse-fly *Glossina palpalis* At the time of commencing this work the state of knowledge was as follows —The experiments of Bruce and Nabarro had proved that the tsetse-fly was capable of transmitting the parasitic micro-organism from an infected animal to one free from the infection if fed on the first, then on the second, with not more than forty-eight hours interval, and, further that tsetse-flies freshly caught in localities where sleeping sickness is rife such as Entebbe, were capable of infecting healthy animals Trypanosomes had also been observed to be present not infrequently in the digestive tract of freshly-caught flies, occurring in enormous numbers in certain regions of the intestine Special interest attached, naturally to these "wild" trypanosomes as they may be termed briefly, meaning thereby trypanosomes with which the fly had become infected in nature, and not as the result of being fed in the laboratory on infected animals Lieuts Gray and Tulloch, of the sleeping sickness commission, had made detailed observations on the wild trypanosomes, and had found them present in about 18 per cent of tsetse-flies caught at Entebbe The wild trypanosomes differed considerably in appearance and structure from those found in the blood or cerebro-spinal fluid of sleeping-sickness patients but not more than was capable of being explained as the result of developmental changes

At that time the late Dr Fritz Schaudinn had just published his well-known memoir on the life-cycle of the trypanosome of the little owl, *Athene noctua*, a work which created considerable stir among all workers upon Protozoa We were therefore, all fully prepared to discover complicated life-cycles involving great morphological changes in these organisms, and had little doubt but that observation would reveal a developmental cycle in the tsetse-fly analogous to that of the malarial parasite in the mosquito It was, moreover, reasonable to suppose that the trypanosomes found in tsetse-flies caught in Entebbe would be the trypanosomes of sleeping sickness, since, as already stated it had been proved experimentally that infection could be brought about by the bites of freshly caught flies When, therefore, we that is, the present writer working in collaboration with Messrs Gray and Tulloch—embarked upon these in-

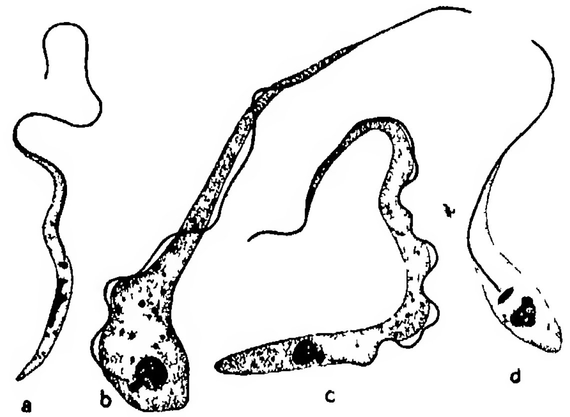

FIG 2 —*Trypanosoma grayi* from the intestine of the tsetse fly *a* male *b* female *c*, indifferent and *d* young forms × 2000 diameters

vestigations, we were fully convinced that the wild trypanosomes found in the tsetse-fly were nothing more than stages in the developmental cycle of *Trypanosoma gambiense*, and that it remained to work out this cycle in full detail and to refer the various forms of wild trypanosomes to their place in it

The methods by which this problem was attacked were partly experimental partly observational By both alike all attempts to establish a relationship between *Trypanosoma gambiense* of sleeping sickness and the wild trypanosomes occurring naturally in the tsetse-fly gave absolutely negative results and forced us gradually and reluctantly, but irresistibly, to the conclusion that the wild trypanosomes of the tsetse-fly have no connection whatever with sleeping sickness but belong to other species quite distinct from *T gambiense*, and innocuous to man

One series of experiments had for its object to determine the exact manner in which the tsetse-fly carries the trypanosome of sleeping sickness from an infected to a healthy animal If the parasite passed through a developmental cycle in the tsetse fly, it might be expected that the latter would show a certain periodicity in its infectiveness, that is to say that

after the fly had taken up the parasites, it would not be ripe, so to speak, to infect a healthy animal until after a certain period of time or a certain number of feeds, as is known to be the case with the mosquito in the transmission of malaria. To test this, and to discover the period necessary for the supposed cycle, batches of flies were fed first on an infected animal and then at regular intervals on a succession of healthy animals (monkeys), using a new healthy animal for each feed. In no case was an infection obtained later than forty-eight hours, although the experiments were extended over three weeks.

On the other hand, conclusive evidence was obtained of the existence of what may be termed direct mechanical infection, that is to say, if a tsetse be allowed to have a partial feed on an infected animal and be then transferred at once to a healthy animal, on which it is allowed to finish its feed, the second animal may become infected. This confirms the results previously obtained by Bruce, both for nagana and sleeping sickness. The experiment was varied by making the fly feed first on an infected animal and then on two healthy animals in rapid succession; it was then found that the first healthy animal became infected but not the second. If the tsetse dips its proboscis for an instant into the skin of a healthy animal, it appears to clean the proboscis and render the fly non-infectious to other animals. This indicates that the direct mechanical transmission is effected by the proboscis alone. As is well known, if a tsetse-fly be fed on an infected animal, then decapitated and its proboscis examined under the microscope, the cavity of the proboscis is seen to contain blood corpuscles and active trypanosomes, a fact which sufficiently explains the direct transmission. The experiments suggest that a tsetse which has fed on an infected subject is only infectious to the first healthy subject bitten by it afterwards.

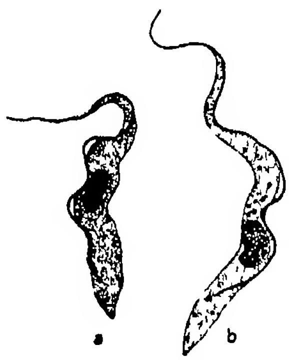

FIG. 3.—*Trypanosoma tullochii* from the intestine of the tsetse fly. × 2000 diameters.

A second series of experiments had for its object to test the connection, if any, between the wild trypanosomes and sleeping sickness. An island called Kimmi, not far from Entebbe in the Victoria Nyanza, was found to teem with tsetse-flies to a degree almost incredible to anyone who has not been there. Although this island was uninhabited and hardly ever visited by human beings, it was found that the tsetse-flies there were more often infected with trypanosomes than on the mainland, since on the average between 7 per cent. and 8 per cent. of Kimmi flies were found to harbour trypanosomes, as against 1.7 per cent. from the neighbourhood of Entebbe. The island of Nsadzi, adjacent to Kimmi, was found to be free from tsetse except in certain limited spots along the shore, and hence served as convenient ground for a camp and station for experimenting upon the flies of Kimmi. The method was to feed a batch of flies caught at Kimmi upon a given healthy experimental animal daily for a certain length of time, then, by dissection and microscopic examination of every fly in the batch, to find out how many of them contained trypanosomes. In this way it was possible to make certain that animals susceptible to sleeping sickness had been fed upon by one or more tsetse-flies containing trypanosomes. Had these wild trypanosomes been identical with those of sleeping sickness, it might have been expected that some at least of the experimental animals would have become infected, but not in a single case did this occur. Attempts to infect experimental animals by direct inoculation of trypanosomes from the intestine of the fly proved equally futile.

The microscopical observation of the trypanosomes within the tsetse-fly led to similar conclusions. If tsetse-flies were fed on animals infected with *Trypanosoma gambiense*, and subsequently dissected and examined after various intervals, it was found that the trypanosomes flourished and multiplied for the first twenty-four hours, becoming at the same time differentiated into two distinct types, the one slender, transparent, and active, the other bulky, granular, and sluggish in movement. Compared with what is known of developmental phases in other Protozoa, the slender forms may be called male (Fig. 1, *a*, *b*), the bulky forms female (Fig. 1, *c*, *d*). Up to forty-eight hours the multiplication continues, and a more "indifferent" type of individual appears. At seventy-two hours, however, the trypanosomes have become greatly diminished, and by ninety-six hours, or slightly later, the trypanosomes have disappeared completely from the gut of the tsetse-fly, this disappearance coinciding with the complete absorption of the blood with which they were taken in. *Trypanosoma gambiense* appears, in short, to have very limited powers of maintaining its existence in the gut of the tsetse, and to be unable to pass forwards into the blood ingested at feeds subsequent to that at which it was taken up by the fly.

In the case of the wild trypanosomes, on the other hand, a very different state of things is found to exist. A study of the forms found in different flies shows that two distinct types occur, one or the other usually being present, though exceptionally both may be found together in the same fly. One of these types, which Novy has named *Trypanosoma grayi*, is distinguished in all its phases by the relatively large size of the smaller mass of chromatin (micronucleus or blepharoplast), which is elongated in a direction transverse to the axis of the body, and placed almost invariably in front of the nucleus (Fig. 2, *a*–*d*). The other type, which we have named *T. tullochii*, is more like *T. gambiense* in its characters, having a small rounded blepharoplast placed well behind the nucleus (Fig. 3, *a*, *b*). Both these types are remarkable for their very great activity, whereby they swarm forwards in the gut of the fly into the blood ingested by it at each feed, and by their own exertions penetrate from the hindmost portion of the gut into its most anterior regions.

The conclusion drawn from these observations is that the "wild" trypanosomes, those found occurring naturally in the tsetse-fly at Entebbe, are not stages of the trypanosome of sleeping sickness, but represent at least two entirely distinct species. It remains to be discovered whence the tsetse-fly obtains these trypanosomes. It may be that the tsetse obtains them from the blood of indigenous animals upon which they are parasitic; *Trypanosoma grayi* has some resemblance to certain trypanosomes of birds, while *T. tullochii* is more of the type of a mammalian trypanosome. It may be, on the other hand, that they are parasites of the fly itself, and have no other host of any kind.

With regard to *Trypanosoma gambiense*, experiment and observation alike show that in Uganda it does not pass through a developmental cycle in the tsetse-fly, but is only transferred mechanically by the

fly's proboscis But the manner in which this trypanosome at first multiplies and develops into male and female forms in the fly's intestine is very remarkable, and suggests the commencement of a life-cycle which is not completed, but which might be so under other conditions In the case of the trypanosomes of fishes, Brumpt has shown that a given species will go through a complete development in a particular species of leech, but only through a part of the development in another species of leech There may be conditions, therefore, in which *T gambiense* would complete the developmental cycle which is seen to begin but appears to be inhibited, in the tsetse-fly in Uganda It must be borne in mind that the sleeping sickness is a new thing, apparently, on the Victoria Nyanza, and has broken out there comparatively recently in epidemic form

In conclusion, there remains only the sad duty of referring to the untimely death of the youngest of the three collaborators in this work, who became himself in some way infected with the trypanosomes which he was studying, and passed away before the results of the investigation were published Only those who knew Forbes Tulloch can gauge the loss and bereavement occasioned by his tragic end

THE WIRELESS TELEGRAPHY CONFERENCE

THE second International Conference on Wireless Telegraphy, which has been sitting during the past few weeks at Berlin, concluded its labours on Saturday, November 3, when the first "Convention radiotélégraphique internationale" was signed by all the representatives of the Powers The States which have signed the convention are the following — Great Britain, Germany, the United States of America Argentina, Austria-Hungary, Belgium Brazil, Bulgaria, Chili, Denmark, Spain, France Greece Italy, Japan, Mexico Monaco, Norway, the Netherlands, Persia, Portugal, Rumania Russia, Sweden Turkey and Uruguay

The first conference, which it will be remembered was only of a preliminary nature was held in Berlin in August, 1903, and a summary of the results then attained was given in NATURE at the time (NATURE vol lxviii p 437) It was there pointed out that by far the most important resolution which the conference had to consider was that making it compulsory on all coastal stations to receive from and transmit to ships at sea all messages irrespective of system and the hope was expressed that private interests would not be allowed to stand in the way of the development of one of the most beneficial of the recent practical applications of science Three years have passed since that conference was held, but the correspondence and articles which have lately been so prominent in the daily Press show that this period has served neither to allay private jealousies nor to enlighten public opinion on the true merits of the case, the same appeals to ignorance and prejudice have been made now by both parties to the dispute as were made then

As the whole question of the justice or injustice of the provisions of the present conference turns on the claims of Signor Marconi, it will not, perhaps, be out of place to recapitulate very briefly the early history of wireless telegraphy In using the expression "wireless telegraphy," we use it in the sense now almost universally accepted of telegraphy by Hertzian waves, as any consideration of earth conduction or magnetic induction methods has naturally nothing to do with the present conference The foundations of wireless telegraphy were laid, as everyone knows, by Clerk Maxwell in the theory which gave rise to the experimental researches of Hertz At the Bath meeting of the British Association in 1888, when the results of Hertz's work were brought to the notice of British men of science by Prof Fitzgerald some experiments by Sir Oliver Lodge on the same subject were also described which showed that he was within an ace of making the same discoveries himself For some time after this experimental work was chiefly devoted to the confirmation and extension of the work of Hertz It was early recognised that there were possibilities about the new discovery which might render it a useful means of telegraphic communication, and suggestions to this effect appeared in 1891 in *The Electrician*, and in 1892 in the *Fortnightly Review* (from the pen of Sir William Crookes)

The practical application of Hertz waves to telegraphic purposes needed, however, the invention of a delicate detecting mechanism What Lord Kelvin did for submarine telegraphy by the invention of the syphon recorder, Lodge and Branly did for wireless telegraphy by the invention of the coherer (1889–1891) From this time onward progress was rapid In 1894 Sir Oliver Lodge demonstrated at the Royal Institution the transmission of signals over considerable distances and through several obstacles But the credit for first establishing the practical utility of the system for demonstrating that it was not merely a new scientific toy lies with Signor Marconi, and to his energy and perseverance we owe it that wireless telegraphy is an art was born in 1896 To his energy, also, and to that of those associated with him, we undoubtedly owe, not only the most extended system of wireless telegraphy of to-day, but also to a large extent the extension of other systems which but for his lead would never have reached their present development Yet no student of scientific progress can doubt for a moment that if Marconi had not stepped in at the critical point some other would have taken his place The work of the true pioneers was done the way into the new country was discovered and it remained only for the most energetic and resourceful to till the virgin soil and reap the plentiful harvest

Now that the reaping of the harvest is in sight we are confronted with the rival claims of the sowers With a wisdom characteristic of the times the Powers have decided that though each may sow and reap for himself he shall conduct his operations in the way most advantageous to civilisation This decision is embodied in the third article of the convention which provides that "coastal stations and stations on shipboard are bound to interchange telegrams without distinction of the system of wireless telegraphy adopted by them" On behalf of the Marconi Company it has been urged that this provision was devised with the express purpose of obtaining for all systems—and especially the Telefunken system—the immense advantages of the Marconi Company's extended organisation On the other hand, there could be no other reason for objecting to this clause than a desire on the part of the objector to establish a monopoly As was pointed out in the article in NATURE to which reference has already been made, the peculiarities of wireless telegraphy render it essential for public utility that there should be either a world monopoly or a perfectly free interchange between competing systems It is not difficult to choose between these alternatives and no one, we venture to think ten years hence will question the correctness of the decision now made

There is little doubt, also, that once it is reconciled to the inevitable, the Marconi Company will realise the very substantial benefits it will obtain, both financially and otherwise. It is clear that the free and rapid growth of any one system will now tend to the development of all; it is clear, too, that the advantageous positions obtained by the Marconi Company on the coasts of the greatest shipping nation of the world will confer on it an inestimable advantage, of which it would surely have been deprived had a monopoly been allowed. It has been several times pointed out in NATURE that State control—and international control—of wireless telegraphy is a necessity, a fact recognised by all nations, and that this control could not be the control of a privately owned monopoly.

In reference to this clause—the only one of first importance—it should be mentioned that certain Powers, amongst them Great Britain, reserve the right to exempt certain stations from its operation on condition that they provide adequate substitutes for the closed stations.

One other proposal of great importance was that brought forward by the United States, that there should be the same obligation for compulsory intercommunication between ship and ship, and a supplementary agreement to this effect was signed by all the Powers except Great Britain, Japan, Italy, Mexico, and Persia. In view of the onerous nature of this obligation on shipowners in the present state of the art, we are inclined to think that the time is not yet ripe for its adoption, though doubtless it will be adopted by all the Powers at some future conference, and in the meantime individual ships have everything to gain and nothing to lose by carrying out its object whenever possible.

The convention also provides for priority of all messages of distress and answers thereto, for equitable division and regulation of charges, and for the establishment of an international bureau for the transaction of administrative work, publication of information, and so forth, but none of the twenty-three other articles deserves special comment. It may be added, though this naturally goes almost without saying, that the convention imposes no restrictions on the naval or military uses of wireless telegraphy. These never were and never could be a subject for international settlement. The various States are pledged to ratify the provisions as quickly as possible, and it is hoped the convention will become operative on July 1, 1908. Between now and then we shall probably hear and read a good deal more about it in Parliament and in the Press, and it is to be hoped that those who write on the subject to the daily Press will make some attempt to understand the technicalities and to study the provisions of the convention.

MAURICE SOLOMON.

NOTES.

THE honours conferred by the King on the occasion of his sixty-fifth birthday appear to be mainly for political services, and there is little recognition of the claims of science. Mr. John Tweedy, president of the Royal College of Physicians, has received the honour of knighthood; Colonel R. C. Hellard, director-general of the Ordnance Survey, and Mr. F. G. Ogilvie, principal assistant secretary (Technology and Higher Education in Science and Art) Board of Education, have been appointed Companions of the Order of the Bath; Colonel D. A. Johnston, formerly director-general of the Ordnance Survey, has been appointed a Knight Commander of the Order of Saint Michael and Saint George; Prof. R. W. Boyce, F.R.S., has received the honour of knighthood, and Dr. J. M. Lang, Vice-Chancellor and principal of the University of Aberdeen, has been appointed a Commander of the Royal Victorian Order.

A STATEMENT has recently obtained currency that the French people themselves, after a hundred years' use of the metric system, cannot claim that it has been adopted throughout France, and a free translation of a circular issued to chambers of commerce in France by the French Minister of Commerce has been employed to support the statement. The Decimal Association in this country recently addressed a letter to the French Minister of Commerce with a view to determine what justification existed for the statement referred to. The Minister's reply makes it clear that the circular is directed only against the use of *old names* in certain trades, and that the English translation misinterprets its meaning and conveys a wholly wrong impression. It is satisfactory to find, in view of such endeavours to retard the acceptance of the metric system by this country, that it has recently been adopted in the works of Messrs. Joseph Crosfield and Sons, Ltd., and steadily grows in popularity.

UNDER the chairmanship of Mr. Lawrence Hardy, M.P., a large and representative conference of fruit growers from the fruit-growing counties of England was held at the South-Eastern Agricultural College, Wye, on November 7. Papers were contributed on planting of fruit trees, strawberries, American blight, and fungus diseases. In the latter paper reference was made to the American gooseberry mildew, the appearance of which in England has been noted by the college mycologist (Mr. Salmon), and a resolution calling upon the Board of Agriculture to take immediate steps to prevent further importation of gooseberry bushes and to destroy infected stocks in this country was unanimously passed. The disease appeared in Ireland in 1900, and has made most extensive ravages in that country, and serious alarm is felt by growers that a similar result may ensue in England unless drastic measures are immediately taken.

SHOCKS of earthquake were felt at Akureiri, Iceland, at 10.20 p.m. on November 8, followed by more shocks of less violence between 1 a.m. and 2 a.m. on November 9.

PROF. W. WIEN, professor of physics in the University of Würzburg, has become chief editor of the *Annalen der Physik* (Leipzig: J. A. Barth) in succession to the late Prof. Drude.

THE Bradshaw lecture of the Royal College of Surgeons will be delivered by Mr. Edmund Owen on Wednesday, December 12, upon the subject of "Cancer: its Treatment by Modern Methods."

A CHRISTMAS course of lectures, adapted to a juvenile auditory, will be delivered at the Royal Institution by Mr. W. Duddell on "Signalling to a Distance, from Primitive Man to Radiotelegraphy" (experimentally illustrated). The lectures will commence on December 27.

IT is proposed, on the occasion of the retirement of Major Craigie, C.B., from the Board of Agriculture and Fisheries, to entertain him at a complimentary dinner on Wednesday, December 12, in recognition of his services to the interests of agriculture and the furtherance of statistical knowledge.

THE balloon *Milano*, of 1000 cubic metres capacity, which started from the exhibition grounds at Milan on Sunday morning, November 11, descended at Aix-les-Bains at

2 p m on the same day, having crossed Mont Blanc The *Milano*, which was piloted by Signori Murillo and Cresti rose to an altitude of upwards of 6000 metres while crossing the Alps

THE Board of Agriculture and Fisheries announces that a horticultural exhibition will be held at Mannheim, in the Grand Duchy of Baden, from May to October, 1907 Exhibits from this country will be admitted to the fruit, vegetable, orchid, and cactus shows Applications for information should be addressed to the office of the exhibition, Friedrichsplatz 14, Mannheim, Germany

AT the annual general meeting of the Mathematical Society on November 8 the council and officers for the ensuing session were elected The list is as follows — *president*, Prof W Burnside, *vice presidents*, Sir Wm Niven, Prof A R Forsyth, *treasurer*, Prof J Larmor, *secretaries*, Prof A E H Love, Mr J H Grace, *other members of the council*, Dr H F Baker, Mr A Berry Mr A I Dixon Prof E B Elliott, Dr J W L Glaisher, Mr G H Hardy Dr E W Hobson Prof H M Macdonald Mr A F Western, Mr A Young

THE *Athenaeum* announces the death in his sixty sixth year of Prof A K Christomanos professor of general chemistry in the University of Athens In 1889 Prof Christomanos became director of the chemical laboratory in the University, and by his efforts it was brought to a high standard of perfection He was the author of a number of works dealing with his special subjects, and also did good work in geology and mineralogy

THE Prince of Monaco is *La Nature* reports arranging for a first international conference on oceanography and marine meteorology to be held if possible, at the time of the inauguration of the museum of oceanography The latter date is not yet fixed, but foreign men of science are being invited to take part in the proposed conference Inquiries and other communications should be addressed to Dr Jules Richard at Monaco

MR JOHN DEVONSHIRE ELLIS who died at his residence at Worksop on Sunday, November 11 was one of the makers of modern Sheffield, and a pioneer in the development of British metallurgy He was the first to adopt the Bessemer process of steel making and introduced many important inventions in the manufacture of armour plates He was vice-president of the Iron and Steel Institute, and in 1889 received from that body the Bessemer gold medal in recognition of the value of his services to the metallurgy of iron

CIRCULARS of invitation have just been issued to the ninth International Congress of Geography to be held at Geneva on July 27 August 6 1908 The president of the congress will be Dr A de Claparède president of the Geographical Society of Geneva vice-presidents Profs R Gautier and R Chodat, and general secretary, M Fernand Tavel Most of the sections of the congress will meet in rooms at the University of Geneva Four languages—German, French, Italian, and English—will be recognised at the congress and memoirs should be written in one of these languages or in Latin Papers and abstracts should be sent in by November 30, 1907

AT the annual general meeting of the Cambridge Philosophical Society on October 29, Dr Fenton, vice president in the chair, the following were elected officers of the society for the ensuing session —*president*, Dr Hobson, *vice-presidents*, Dr Baker, Dr Fenton, Mr D Sharp *treasurer*, Mr H F Newall, *secretaries*, Mr A E Shipley, Rev F W Barnes, Mr P V Bevan, *new members of the council* Prof Larmor, Prof Thomson, Dr Duckworth, Mr W G Fearnsides

A REUTER message from Paris states that M Santos Dumont made further trials of his airship on Monday in the presence of members of the committee of the Aéro Club and numerous spectators At the second trial two wheels of the apparatus left the ground and in five and one-fifth seconds the machine travelled a distance of about 500 metres in the course of which it rose four times At another trial the aeroplane started off followed by a motor car conveying the members of the committee It rapidly covered 500 metres, proceeding by successive bounds and soon outpacing the motor car The committee, on measuring afterwards the distances traversed, found that the aeroplane after reaching a height of between four and five metres, had traversed in level flight a distance of 220 metres without touching the ground in twenty-one and one fifth seconds thus travelling at the rate of about ten metres a second The best time recorded was seven and one fifth seconds over a distance of 82 60 metres representing a speed of about 40 kilometres an hour

MALARIA in Greece was the subject of a paper read by Major Ronald Ross F R S before the Oxford Medical Society on November 9 Prof Ross described the valley of Lake Kopais in Bœotia the scene of his recent study of malaria in Greece The locality was the dried-up bed of a large lake drained in remote times but in the Middle Ages reverting to marsh once more owing to the drainage works falling out of repair Recently restoration has been taken in hand and the bed of the ancient lake is now a fertile plain covered with crops of all kinds but the inhabitants are decimated by malaria the type of disease being very severe pernicious attacks common and black water fever extremely common In five localities the minimum malaria-rate among children was found to range between 25 5 per cent and 40 9 per cent Prof Ross considers that the country is eminently suited to the application of drainage measures for the eradication of the disease A Grecian malaria society has commenced the work with energy and an appeal for funds on behalf of the scheme has been issued by the Liverpool School of Tropical Medicine and is under the patronage of Princess Christian

THE *Daily Chronicle's* correspondent at Rome reports that Prof Waldstein's international project for the excavation of Herculaneum has gained the unanimous adhesion of the Royal Commission of Antiquities and Fine Arts in Rome under the following conditions among others — (1) Subscriptions are to be of a private character without the official intervention of foreign States and the funds are to be administered by an International Committee centred in Rome (2) An executive commission is to be constituted of foreign members representing the contributing countries and Italian representatives (3) All scientific material to be published first of all under the supervision and at the expense of the Italian Government the Minister of Public Instruction being empowered to invite the co operation of national and foreign publishing houses (4) All objects excavated to be the absolute property of the Italian Government, which however will retain the faculty of conceding to foreign States according to the measure of their respective generosity as contributors to the exploration fund, duplicates and other finds where this can be done without prejudice to Italy's national collections

AT the inaugural meeting of the new session of the Institution of Civil Engineers on November 6, the president, Sir Alexander Kennedy, F R S , delivered an address on the relation of the engineer and engineering to the world at large In relation to science, he pointed out that not a few engineers spend their whole lives in what is really scientific work, while nominally only earning their daily bread in ordinary mechanical pursuits The paths of the artist and the engineer seem too often to be divergent, but as soon as engineering works are treated on their own merits, and not as if they are mistaken imitations of other things, it will be found that they can possess even artistic as well as other merits Everyone now recognises that there is a dignity in a *Dreadnought* which is almost majestic, and that a modern liner forms really as fine a subject for a picture as a full-rigged ship In concluding, the president spoke of the future of engineering and of the possibility—which he thought a very small one—of finding anything in mechanical science corresponding to the "survival of the fittest," or any traceable lines along which mechanical evolution takes place Invention forms such a disturbing influence in engineering evolution that any prophecy on evolutionary lines is impossible It is still more useless to attempt to forestall the future by trying to do to-day what it is supposed that other people may try to do twenty years hence The *Great Eastern*, broken up for scrap almost within hail of the *Carmania* was a pathetic tragedy, from this point of view in engineering

EDUCATIONAL Leaflet No 22 of the National Association of Audubon Societies is devoted to an account of the blue jay (*Cyanocitta cristata*) by Mr W Dutcher, the president of the association It is accompanied by a coloured plate of the bird

THE greater part of the September issue of the Proceedings of the Philadelphia Academy is taken up by the description of a large collection of Orthoptera from Montana Utah, Colorado and the Yellowstone Park The authors of the paper are Messrs J A G Rehn and M Hebard of whom the second made the collection Many new forms are described

OF two zoological articles included in Nos 6 and 7 of the fifth volume of the *Boletin de la Sociedad Aragonesa de Ciencias Naturales*, the first, by the Rev R P Longinos Navas, is devoted to abnormal hens' eggs of which several are figured in a coloured plate Some of these appear to be of the type not uncommonly met with in the case of old birds about to cease from laying One however, is remarkable for its rose-red colour, due it is supposed to the parent hen having fed on a particular kind of bulb In the second three new Spanish Neuroptera are described one forming the type of a new genus

IN an address delivered to the Hull Scientific and Field Naturalists' Club at a conversazione held on October 17 Mr T Sheppard the president took for his subject the relationship between provincial museums and local scientific societies The address has been published in the Transactions of the club, and reprinted in pamphlet form as No 36 of the Hull Museum Publications Hull, it appears is very fortunate in respect to the good relations existing between the municipal museum and the local scientific society this good fellowship it is stated, being of special value to the museum and likewise, in a minor degree, conducive to the interests of the ratepayers In many other towns the relationship is, however, according to Mr Sheppard, of a less satisfactory nature, the museum officials ignoring the work and disdaining the assistance of the amateurs Neither is it considered advantageous for the museum to be "run" by the local society, such an arrangement tending, it is urged, to check donations owing to want of security as to the permanency of the former

ACCORDING to *La Nature* of November 3, Brussels is about to inaugurate a new era in the matter of fresh-water aquariums by the opening of a building in the Avenue Louise The new institution is not intended to be a merely popular exhibit, with a few tanks in which a certain number of more or less unhealthy-looking fishes are shown On the contrary, it is purposed to display, as time goes on, the complete fresh-water fauna of Belgium in suitably constructed basins and tanks, including, of course, those distinctive of rivers, lakes, and ponds Nor will the flora be neglected, the scheme being to show as much of this as is found practicable The central salon will resemble a winter garden, with a large central basin and tanks let into the walls In some of these tanks will be shown examples of all the indigenous fresh water fishes while others will be devoted to the exhibition of crustaceans molluscs, batrachians, reptiles, worms, insects, and plankton It is hoped that the institution will prove, not only an attraction to the general public, but that it will have a definite scientific value, and will also aid in the re-stocking of the depleted Belgian rivers with fish Acclimatisation is to be a feature of the aquarium, in which a tank will be reserved for the American cat-fish, preparatory to introducing that species into the rivers of the country

THE history and origin of zoological gardens and natural history museums forms the subject of a long article by Mr J von Pleyel in *Naturwissenschaftliche Wochenschrift* for October 28 Menageries, in the author's opinion, owe their origin partly to the cult of sacred animals and partly to the ambition of rulers to possess specimens of rare and valuable creatures from foreign lands or savage ones from their own In their simplest form zoological gardens were indeed, one of the earliest developments of culture and were familiar to the Chinese, Indians, Greeks Romans and pre-Spanish Mexicans in very ancient times The oldest recorded menagerie is as might be expected Chinese dating from 1150 B C The den of lions kept by Darius as described in the Book of Daniel, is an example of one of these primitive menageries, while the cult of sacred white horses by the ancient Greeks and Romans, and that of so called white elephants in Burma and Siam, are instances of a second type After a survey of the records of establishments of this nature during the Middle Ages and immediately succeeding periods, the author refers to the typical menageries of modern times, incidentally mentioning that a live giraffe was received at Schönbrunn so early as 1828 The Paris establishment is regarded as the earliest entitled to the designation "zoological gardens," in the modern sense of that term which owes its origin, however, to the foundation of the menagerie in the Regent's Park Of German establishments of this nature, the one at Berlin is the earliest

THE causes producing a cessation of vitality in old trees are imperfectly, if at all, understood There are various interesting problems concerned with this question, notably the continued propagation of trees by vegetative methods In this connection Mr R S Hole is contributing an article on pollard-shoots, stool-shoots, and root-suckers to the *Indian Forester* (July and August) It seems probable

that root-suckers play an important part in the regeneration of some Indian trees, and the author instances the production of practically pure woods of *Diospyros tomentosa* and *Ougenia dalbergioides* by this means, so that the subject is worthy of careful inquiry and observation

THE September number of the Quarterly Journal issued from the Liverpool University Institute of Commercial Research in the Tropics deals mainly with agriculture on the west coast of Africa Viscount Mountmorres writes a eulogistic article on the results achieved by the Gold Coast Department of Agriculture, comparing the gardens at Aburi very favourably with the gardens at Konakry, in French Guinea Rubber and cacao are the primary products at Aburi, and the instruction of the natives in their cultivation and preparation is an important branch of the work An account of the agricultural resources of the Ivory Coast, contributed by Mr E Castaing, provides interesting information as to the commercial varieties of the indigenous rubbers, the nature and uses of kola nuts, and the native method of preparing palm-oil

AN account of the red-rot disease of sugar-cane caused by the fungus *Colletotrichum falcatum* occupies a considerable portion of the third memoir of the Department of Agriculture in India which deals with fungus diseases of sugar-cane The author, Dr E J Butler, adduces evidence to show that the disease generally originates in the lower part of the plant, producing eventually characteristic red streaks in the vascular tissues Amongst other fungal pests, Dr Butler describes two stem diseases attributed to new species of Cytospora and Sphæronema and a more serious leaf spot disease caused by a species of Cercospora also differing from species hitherto recorded

THE Department of Commerce and Labour Washington, has issued a report on the blind and deaf (including the deaf and dumb) in the United States the data having been collected in connection with the twelfth census (1900) At the census itself, however, the work of the enumerators was restricted to a brief preliminary return showing the name, sex, age, post-office address, and nature of the existing defects in all persons alleged to be blind or deaf More detailed information was then obtained by direct correspondence with the individuals named in the primary returns, or with their parents or guardians, questions being asked as to the total or partial character of the defect, the age at which the defect, if not congenital, was first remarked, the supposed cause, the relationship if any, between the parents, the relatives who were similarly defective, and the school, if any, at which the defective person had attended It is from the data contained in these personal returns that the report is compiled Dr Alexander Graham Bell is responsible for the scope and conduct of the investigation, and the text of the report relating to the deaf It may be noted that of the blind whose parents were cousins 25 per cent were congenitally blind, whilst of the blind whose parents were not so related only 7 per cent were congenitally blind Similarly, of the deaf whose parents were cousins 42 per cent were congenitally deaf, whilst of the deaf whose parents were not so related only 15 per cent were congenitally deaf The report is a valuable one, with much more, and more trustworthy, information than has yet been obtained in any similar investigation but it suffers from a common defect, viz the lack of comparative information of a similar kind relating to the non-defective, which is essential to a proper interpretation of the results, this especially applies to the statistics relating to defective relatives and to the consanguinity of the parents The need is only partially met by the comparative figures for congenital and non-congenital defectives

A NOTE by Signor Alessandro Artom on his system of wireless telegraphy, first invented in 1903, is contributed to the *Atti* of the Lincei Academy xv (1), 12 The peculiarity of this system is that by the use of two aerial conductors instead of a single antenna an unsymmetric electromagnetic field is produced, and it is thus possible to send messages in definite directions Experiments have been made with the cooperation of the Italian naval authorities, chiefly between Monte Mario (Rome) Anzio (distant 55 km), and the island of Maddalena By varying the orientation of the aerials, communication could be established or cut off at will

THE new "Dolomiten Strasse" brings many of the most interesting portions of the Dolomite region within easy access Leaving Cortina, it rises rapidly over the Col di Falzarego, passing over a shoulder of Monte Nuvolau and affording a fine distant view of the Marmolata ice fields It then descends rapidly to Pieve Livinallonga where it skirts the hill-side at a considerable height above the valley, and it next rises by zigzags to the top of the Pordoi Pass, passing close by some of the most interesting members of the Sella group From here it descends to Campitello, whence Botzen may be reached *viâ* the Karersee The new road is completed with the exception of the portion from the Col di Falzerego to Cortina, where the old road is available for vehicular traffic

A "NATURE-KNOWLEDGE DIARY," compiled by Mr W Percival Westell, has been published by Messrs Blackie and Son Ltd Provision is made for plotting the daily barometer readings on a suitably numbered squared paper chart, but it does not seem to have occurred to the compiler that thermometer readings are also worth plotting, and that the same charts can be used for this purpose The general arrangement of the blank forms for recording observations of which the diary is almost entirely made up is likely to prove convenient The price of the book is 6*d* net

THE eighth edition of Prof R Hertwig's "Lehrbuch der Zoologie" has just been published by Mr Gustav Fischer Jena The work originally appeared fifteen years ago and was reviewed in NATURE of June 22 1893 (vol xlviii p 173)

OUR ASTRONOMICAL COLUMN

DISCOVERY OF A NEW COMET —A telegram from the Kiel Centralstelle announces the discovery of a new comet at Copenhagen on November 10 Its position at 17h 35m (Copenhagen M T) was

$$\text{R A} = 9\text{h}\ 16\text{m}\ 32\text{s},\ \text{dec} = 12^\circ\ 28'\ 31''\ \text{N}$$

and it is travelling in a north-easterly direction The daily movement is given as +4 2m in R A and +1° 10′ in declination When discovered, the comet was about 8m west of ε Leonis, and is therefore travelling towards the constellation Leo Its position rises, at present at about 11 p m

A second telegram from the Centralstelle informs us that this object was observed by Herr Rheden at Vienna on November 11 its position at 16h 75m (Vienna M T) being

$$\text{R A} = 9\text{h}\ 20\text{m}\ 9\text{s}\quad \text{dec} = +13^\circ\ 35'\ 25''$$

Unfortunately no idea of the comet's brightness is given in these telegrams

THE TELLURIC LINES IN THE SOLAR SPECTRUM —M Štefánik is proceeding with his researches on the direct observation of the infra-red portion of the spectrum, and publishes an account of his most recent results in a communication to the Paris Academy of Sciences (*Comptes rendus*, No 17) After briefly reciting the history of our knowledge of the telluric bands and lines, the author describes the two spectroscopes with which he carried out his researches at Chamonix, at the Grands-Mulets, and on the summit of Mont Blanc In each case he employed the red screens which he has previously described, and by this means was able to see the region of the spectrum which extends from about B to 1 μ On July 21, at the Grands-Mulets, he observed the setting sun with his prism spectroscope and found that as the sun sank lower the group *a* was unequally strengthened in parts, whilst several feeble bands became visible between *a* and A The groups *Z*, X, *and* Π *were successively reinforced, notably more so as the* sun sank into the haze gathered at the horizon Similar observations made with the grating spectroscope at the summit of Mont Blanc on July 30 gave similar results and a feeble band appeared between the groups A and *Z* The *increase in intensity of the groups Z and* π was so considerable that their telluric origin was very obvious Zenith observations revealed changes which in general were of the opposite character At all three stations M Štefánik obtained a number of photographs when the sun was *highest and at the horizon respectively*, with both spectroscopes

THE NUMBER OF THE VISIBLE STARS —The total number of stars usually supposed to be visible in the largest telescopes and on the best photographs is about one hundred million, but according to a computation recently made by Mr Gore this number must be accepted as the outside maximum To obtain his results Mr Gore made a number of counts on the photographic prints given in the late Dr Roberts's volume of stellar photographs, and found that the average number of stars per square degree was 4137 in the Milky Way 1782 near the Milky Way and 406 in the non-galactic regions Combining these results with the estimated areas of galactic and non galactic regions published by Prof E C Pickering, he obtained as the grand total of visible stars the number 64 184 757 This is probably smaller than the actual total, as some of the fainter star images would probably be lost in the reproduction of Dr Roberts's photographs

Clusters and nebulæ were avoided in making the counts, so that Mr Gore's total will have to be increased on this account In another count the average richness of the irregular clusters came out as 5752 stars per square degree but this is far below the average richness of the globular clusters, one of which ω Centauri shows 25 000 stars per square degree (*Observatory*, No 376)

STARS WITH PECULIAR SPECTRA —In No 4129 of the *Astronomische Nachrichten* Dr H Ludendorff discusses the spectra of the stars R Coronæ Borealis 12 Canum Venaticorum and 72 Ophiuchi which he and Dr Eberhard have photographed with the three-prism spectroscope (No iv) of the Potsdam Observatory The remarkable feature in the spectrum of R Coronæ is the non-appearance of the hydrogen lines $H\beta$, $H\gamma$ and $H\delta$ as the H and K lines are broad the absence of $H\epsilon$ cannot be affirmed but on a smaller scale spectrogram the ultra-violet lines of hydrogen do not appear From the measurement of about thirty or forty lines on each of five spectrograms, Dr Ludendorff finds the radial velocity of this star to be about +24 6 km as compared with Prof Frost's value of +14 km The present values were however obtained during a period when the star was at its normal brightness whereas Prof Frost's referred to a period when it was fainter It thus appears that the radial velocity may vary during the epochs of magnitude changes

In the spectrum of 12 Canum Venaticorum, Dr Ludendorff suspects changes in various chromium and iron lines The magnesium line λ 4481 also appears to vary and, whilst he can find no reason for the variation Dr Ludendorff suggests that this may be analogous to a similar phenomenon which Sir Norman Lockyer has pointed out in the spectrum of α Andromedæ both stars being of the Markabian type

AN INTERESTING VARIABLE STAR —In No 4126 of the *Astronomische Nachrichten* Prof Barnard publishes the results of his visual observation of a variable situated in the brightest part of the cluster M3 (N G C 5272)

Observations were made on 112 nights since March, 1899, and from the results the period was found to be 15 77594 days The maximum magnitude of this object is about 12 0, and it varies through about two magnitudes

CATALOGUE OF DOUBLE STARS —Prof Doberck continues the results of his double-star observations at the Hong Kong Observatory in Nos 4130–1 of the *Astronomische Nachrichten* The present list is similar in form to those previously published, and contains the results for about 170 stars

THE TENTH INTERNATIONAL GEOLOGICAL CONGRESS

THE tenth International Geological Congress met this year in Mexico, and the proceedings connected with it extended altogether over a period of nearly two months Elaborate arrangements for the reception and entertainment of the members were made by the Mexican authorities, the President of the Republic, General Porfirio Diaz, himself manifested a lively interest in the work of the congress and desired that everything possible should be done to make it successful Over and above this, liberal financial assistance was rendered, the Mexican Government bearing half the cost of the steamer and railway fares of those attending the meeting

In all more than six hundred membership tickets were issued, members resident in Mexico of course predominated, and second place was taken by those from the remainder of the North American continent, of European countries, Germany was most strongly represented which was perhaps natural in view of the large number of Germans who are engaged on the Mexican Geological Survey It was surprising to find so few British representatives present considering the great attractions which the country offers both to the geologist and to the mineralogist, all told there were not more than five members who could reasonably be said to be representative of British science, and not one of these was officially delegated to the congress This apparent indifference did not pass without comment on the part of the Mexican officials

Several fairly long excursions, which will be referred to later, were arranged to take place before the meetings, but the formal proceedings of the congress began with the meeting of the council on the morning of Thursday September 6 when the general arrangements were finally settled and a programme of papers &c , was drawn up for approval at the opening session, this took place the same forenoon in the hall of the old Minería (now part of the National School of Engineering) This meeting was presided over by President Diaz who also at the conclusion of the business, formally declared the congress open In addition to the speeches of welcome and addresses by the retiring president and the president-elect the only business consisted in the approval of the proposed programme and of the proposed executive committee The principal offices in the executive were filled by the election of the corresponding officers of the provisional committee in Mexico, as follows —*president*, José G Aguilera, director of the National Geological Institute (the Geological Survey), *general secretary* Ezequiel Ordoñez and *treasurer*, Juan D Villarello both of whom are also on the Survey

The first of the ordinary meetings (which were held in the newly-completed National Geological Institute) took place on the afternoon of Thursday, September 6, under the presidency of Prof Credner (Leipzig) A letter was first read from Mr Karpinski (St Petersburg) accompanying a copy of his memoir on "Les Trochilisques"—doubtful fossils occurring only in the Devonian—after which Mr G H Heilprin read a communication on "The Occurrence and Interrelation of Volcanic and Seismic Phenomena," in which he maintained the view that shocks of tectonic origin are scarcely to be dis-

tinguished from those of volcanic origin, seismic phenomena are often preceded and accompanied by magnetic disturbances This view was combated, however, by Prof Lawson and Dr Becker, while Mr H F Reid held that the available data are quite insufficient for deciding the point Dr K Renz (Breslau) next read a paper, "Ueber das ältere Mesozoicum Griechenlands," adducing reasons why certain marbles hitherto referred to the Cretaceous might be transferred to the Trias

Several papers the titles of which appeared on the programme were abandoned or postponed owing to the absence of their authors

It had been arranged that the meetings of the congress should take place only on alternate days, the intervening days being devoted to sight-seeing and excursions, so the second meeting did not take place until the forenoon of Saturday, September 8, when Prof Diener (Vienna) occupied the chair The first business was a statement by Dr Adams (Montreal) regarding the general geological map of North America, of which copies (each consisting of four large sheets, scale 1 5,000 000) had been previously distributed to the members This map has been prepared in accordance with the instructions of the Geological Society of America, which at its last meeting in Ottawa, appointed a committee (members —J C Russell (president) J G Aguilera, Bailey Willis F Adams C W Hayes) to carry the matter through The expense was borne by the Geological Survey of the United States, the Mexican Government assisting by purchasing a large number of copies for presentation to the members of the present congress Explanatory notices are provided by Messrs Bailey Willis and Aguilera The nomenclature adopted is that of the United States Survey and at the meeting this called forth a certain amount of criticism from Prof Lawson (California) especially with reference to the use of the term "Algonkian"

The remainder of the forenoon meeting and the greater part of the afternoon meeting were devoted to papers and discussion on "The Climatic Conditions during the Geological Epochs" The first contribution was made by Prof J W E David (Sydney) who discussed the glacial phenomena more especially of Australia but also of India South Africa and South America He was followed by Prof Frech (Breslau), "Ueber die Klimaänderungen der geologischen Vergangenheit" From Palæozoic times up to the present there has always been a correlation between the climatic evolution of the earth and the proportion of carbonic anhydride and of water vapour present in the atmosphere Increases are due to volcanic exhalations and diminutions to the formation of organic and more especially of inorganic compounds

At the afternoon meeting of September 8 presided over by Prof Frech the general discussion was opened by Dr E Philippi (Berlin) and was continued by Messrs C Burckhardt (Mexico) Frech A Rothpletz (Munich) C Diener F v Kerner (Vienna) Vorwerg (Herischdorf) A P Coleman (Toronto) and M Allorge (Oxford), it is impossible however, to give in the space now available even a short review of the discussion The general results were summed up by the chairman who considered that the following might apparently be accepted as well-ascertained facts —the existence of a Permo-Carboniferous Glacial epoch uniformity of climate during the Triassic and the Jurassic the existence of zones of climate since the Middle Cretaceous and a gradual diminution of temperature during the Ternary and the Quaternary

This was followed by a paper by General J de Lamothe (Grenoble) on "Le Climat de l'Afrique du Nord pendant les Periodes Pleiocène et Pleistocène" after which Prof Stefanescu (Bucharest) gave a description of the skeleton of *Dinotherium gigantissimum* (Stefanescu) a new species discovered by him in 1888, and, finally a study by Mr Hilgard on "The Causes of the Glacial Epoch" was contributed by Mr M Manson

The discussion on climatic conditions was reopened at the next meeting on Monday September 10, when Dr Becker presided The point chiefly dealt with was the question as to the causes which led to extensive glaciation in parts of the earth's surface where under present conditions, an extensive snowfall is difficult to explain The principal speakers were Messrs W M Davis (Harvard) H L Fairchild (Rochester), Heilprin (Washington) David and Frech

The remainder of the forenoon meeting on September 10 and part of the afternoon meeting (under the presidency of Prof Tschernyscheff, St Petersburg), were devoted to the subject of the formation of ore deposits, but many of the papers announced in the programme were abandoned The first paper was by Mr H F Bain (Illinois), on "Some Relations of Palæography to Ore Deposition in the Mississippi Valley," and led to some discussion as to the possibility of soluble salts of the heavy metals reach ing the sea there to be deposited by secondary action In his communication "Sur la Relation entre l'État propylitique (Grunstein) des Andesites et la Genèse des Filons liés à cette Roche," Mr B v Inkey (Domotori) showed that the formation of the Grunstein which is so characteristic for the metalliferous veins of Hungary (and also as Prof Kemp pointed out for those of the Sierra Nevada) is due chiefly to the chloritisation of the black augite and hornblende of the original andesite, and results from an action quite different from the kaolinisation along the veins themselves This paper also gave rise to considerable discussion Prof J F Kemp (New York) read a paper on "Ore Deposits at the Contacts of Intrusive Rocks and Limestones and their Significance as regards the General Formation of Veins" holding that the evidence indicated that part of the material for the mineral formation must have been brought in by water which probably came from the intrusive magma Other papers, which however did not give rise to much discussion were contributed by Mr Villarello (Mexico) "Sur le Remplissage de quelques Gîtes metallifères" Mr W H Weed (Washington) "The Origin and Classification of Ore Deposits" and Mr Lindgren "The Relation of Ore Deposits to Depth"

Three papers illustrated by lantern pictures followed the first by Mr G Andersen dealing with the Swedish Antarctic Expedition was contributed by Prof Sjogren the second, by Mr Heilprin dealt with the eruption at Martinique whilst the third by Dr Tempest Anderson (York) dealt with that of St Vincent

At the Wednesday's meeting September 12 presided over by Prof Rothpletz Prof Konigsberger (Freiburg i B) read a paper "Ueber den Verlauf der Geoisothermen in Bergen, und seine Beeinflussung durch Schichtstellung Wasserläufe und chemische Processe" In the course of this he showed how by means of a special apparatus devised by him variations of underground temperature might be measured accurately and indications obtained by which volcanic eruptions might be foretold This led to a discussion in which Messrs Becker Schmidt (Stuttgart), Günther (Munich) and von Kerner (Vienna) took part Thereafter Prof Keilhack (Berlin) discussed the mode of formation of the onyx bed at Etla Oaxaca (Mexico) and Mr Diaz (Colima) gave particulars regarding the volcano of Colima pointing out that there was apparently a periodicity in its activity It was announced that the discussions on "The Nomenclature and Classification of Rocks" and on "The Relations between 'Tectonique' and Eruptive Masses" would not be proceeded with

Various resolutions of the council were approved namely that the new subject for the Spendiaroff prize be "The Description of a Fauna with Reference to its Geological Evolution and its Geographical Distribution" re-approval of the proposal to create a model institute of geophysics the institution of a special commission to study the variations of the geothermal degree

The concluding items were a lecture by Mr Sabatini (Rome) on "La dernière Éruption du Vésuve" and another by Dr Tempest Anderson on the same subject these were accompanied by lantern illustrations

There was no afternoon session

The last meetings took place on Friday September 14 At the forenoon session Mr C W Hayes (Washington) presiding the most important matter dealt with was "The Earthquake of San Francisco" introduced by Prof Lawson whose paper was followed by a discussion in which Messrs Frech T L Ransome (Washington) and H F Reid (Baltimore) took part The other papers were on "Interglacial Periods in Canada" by Prof Coleman "Geologic Classification in the North-Central

Portion of the United States," by H N Darton (Washington)", "A Meteorite Crater of Arizona" by Prof Fairchild

The afternoon meeting was presided over by the president, Mr Aguilera Only two papers were communicated, one at the beginning by Prof David, on "The Occurrence of Diamond in Matrix at Oakey Creek, Inverell New South Wales," and one at the end by Mr E O Hovey (New York) on "La Sierra Madre Occidentale de l'Etat de Chihuahua," which was illustrated with lantern views The intervening period was taken up with reports and general business Prof Reid gave a *resumé* of the report of the International Glacier Committee, of which he is president No report having been received (though asked for) from the committee on the geological map of Europe a motion was carried regretting the omission The secretary read a report by Sir Archibald Geikie, president of the committee on cooperation in geological investigation, which was approved It was announced that the committee of the Spendiaroff prize had awarded this to Prof Tschernyschéff for his work on "Die obercarbonischen Brachiopoden des Ural und des Timan" Prof Frech presented the report of the committee on the "Palæontologica Universalis" and its proposal to extend the scope of its publications was unanimously approved, several new American and Mexican members were elected to the committee

Prof Sjogren then invited the congress to hold its eleventh session at Stockholm, and in 1910 instead of 1909 The invitation was accepted with acclamation and it was agreed to leave the date to be fixed by the Swedish committee (In view of the British Association meeting at Winnipeg in 1909, the later date would be preferable so far as British geologists are concerned)

Hearty votes of thanks to the Mexican Government and the organising committee were passed on the motion of Prof Stefanescu and Mr Sabatini They were responded to by Mr Aguilera who thanked the foreign geologists for coming so far to make the congress a success and invited them all to meet again at Stockholm This closed the formal business of the congress

A number of very interesting excursions had been arranged in connection with the congress They were of two kinds—one-day excursions between the meetings, and long excursions of from three to twenty days' duration which took place before and after the congress proper The former were free of expense to the members and for the others an inclusive charge which averaged about fifteen shillings *per diem* was made the greater part of the expense being borne by the Mexican Government

The first one-day excursion was devoted to the City of Mexico itself the members being driven about the town and shown the museums and other public institutions On the Sunday a long day was devoted to Cuernavaca and this proved to be probably the most interesting of all After journeying for some miles over the plain in which Mexico stands at an altitude of nearly 7500 feet, there is a stiff ascent of the range which bounds this plain, the railway reaching an altitude of almost 10,000 feet Cuernavaca lies nearly 5000 feet down on the other side and the steep, winding descent is very picturesque From near the summit magnificent views are obtained over the lower plain from which rise numerous volcanic cones and ranges apparently but little changed from the time of their formation, the whole stretches out before the observer just like an immense relief map On the map, the distance from Mexico to Cuernavaca is barely forty miles, by rail it is seventy-five and the double journey takes more than nine hours The town itself has one of the finest situations in Mexico and is a favourite resort Cortes built his country palace there and on its terrace the congress was entertained to a banquet by the Municipal Council

Another day was spent in visiting the Toltec remains at San Juan Teotihuacan Here there are two pyramids (of the sun and the moon) and the remains of many other interesting structures After inspecting these, the members lunched in the "Grotto Porfirio Diaz" a large natural cavity formed under an ancient lava flow in the neighbourhood

The last of these excursions was to the celebrated silver district of Pachuca, where visits were paid to various mines and works, in these the celebrated "patio process" was seen in operation on a large scale

Four of the long excursions took place before the congress opened One, of nine days' duration, was to the south, and visited, in addition to various districts of more purely geological interest, the famous Mitla ruins near Oaxaca Another, of three days, went east to Vera Cruz, on the coast, returning by Orizaba over the celebrated picturesque route of the Mexican Railway (known as "The Queen's Own" from its British origin), with its difficult engineering and striking scenery The remaining excursions had special attraction for vulcanologists On the one, the principal points of interest were Jorulla and Toluca, though the whole excursion lasted for thirteen days, while the last, of twelve days' duration, had Colima as its principal attraction

In connection with these excursions, the greatest pains had been taken to make the visits as enjoyable and profitable as possible Special trains, conveyances, and riding horses were provided detachments of the famous *Rurales* (a kind of military gendarmerie) attended to the safety and comfort of the travellers, where hotels were not available on the cross-country journeys, camp equipment was sent in advance or the proprietors of *haciendas* were called upon for hospitality The travellers, therefore, performed their journeyings under exceptionally favourable conditions It was not possible to carry out the full programme in every case, however, as the excursions took place during the rainy season, which this year has been somewhat exceptional At the same time, the difficulties or dangers were not nearly so great as, it appears, the sensational accounts in some European papers would lead one to believe was the case

The principal excursion took place after the congress from September 15 to October 4 The field covered extended from Mexico City right up to Arizona in the north and down to Tampico in the east and the distance travelled amounted to three or four thousand miles The members taking part were accommodated in two special Pullman trains which served both as means of conveyance and as hotel The route was arranged so as to include a very wide range of interesting ground, so that all tastes were catered for Numerous mines were visited—sulphur silver copper, lead, and coal—also oil wells various smelting and separation processes were seen in operation extinct craters were inspected and fossiliferous beds were searched for specimens and, in addition, there was the general interest peculiar to the country itself to say nothing of the splendid hospitality everywhere encountered It is impossible to enter into details of the trip but two striking features may be mentioned The first is the great stretch of semi-arid region towards the north of the Republic through which the railway passes for hundreds of miles This is practically level, and consists of a series of "Bolsons," which at first sight look as if they must have been of lacustrine formation The evidence is entirely against this however and the supposition is that though the first depositions may have taken place in shallow lakes these were soon obliterated and the great bulk of the deposit was levelled out simply by the rush of surface water during the rainy seasons From the plains thus formed the mountains rise with startling abruptness as from a sea, sometimes with fantastic outlines, so that the traveller could almost imagine he was sailing some distance off a mountainous coast like that of Norway Even more interesting were the opportunities afforded for studying geological structure on a large scale The mountain ranges are generally bare of vegetation and overlying material, so that the contortion folding and faulting of strata formation of anticlinal valleys &c can be observed with the greatest ease This was particularly noticeable along the railways in the neighbourhood of Monterrey and it was a matter for regret that arrangements had not been made for the train to stop at various points to enable the photographers of the party to make proper exposures, good photographs of many of the structures observed would have possessed all the lucidity of geological diagrams with the additional advantages which pertain to truthful representations of actual structures

A special side excursion had been arranged for those members of the party specially interested in mining and metallurgy. These, as the guests of the Copper Queen Co., left the main body at El Paso, on the frontier, and travelled west to Bisbee (Arizona), Cananea (Sonora, Mexico), Douglas (Arizona) and Nacozari (Sonora), visiting the various copper mines and smelting works at these places, and then rejoining the main party.

Although by that time the rainy season was supposed to be nearly over, the members taking part in the northern excursion also had some experience of the difficulties caused by "wash-outs," &c., in a country like Mexico, and at several places the programme had to be curtailed owing to delays to the trains.

The last event of all was an excursion of a week's duration made by a party of sixty or seventy members, who left Mexico City on October 6 to visit the Isthmus of Tehuantepec as the guests of Sir Weetman Pearson, whose firm have constructed the railway and docks which now serve as a means of communication between the Atlantic and Pacific coasts of the Republic at its narrowest part.

As has been indicated, the members of the congress were everywhere received with the greatest hospitality on the excursions as well as in the capital. One of the many social functions during the meeting may perhaps be allowed special mention; this was the reception of the members by President and Madame Diaz in the famous Palace of Chapultepec ("The Hill of the Grasshopper"). After having been welcomed by their hosts, they spent some time admiring the magnificent views from the upper terraces, including the city and the distant snow-capped peaks of Popocatapetl and Ixtaccihuatl. In the evening they were entertained to a banquet on the lower terrace; they had been invited "to tea," but tea appeared to be the one thing which was not provided.

The meeting of the congress was in all respects a very great success, and for this the Mexican officials, both of the Government and of the congress, deserve the highest praise. While all did well, it is no disparagement to the others to say that thanks are specially due to the general secretary, Mr. Ordoñez, for the admirable manner in which he filled that responsible and trying position.

METEOROLOGICAL NOTES

THE frequency of thunderstorms in relation to the sun-spot period is discussed by Dr. Aksel S. Steen in a reprint from the "Hann Band der meteorologischen Zeitschrift." The author has dealt with data from Norway, Sweden and Denmark, using material from twenty, twenty-eight and eight stations in each country respectively, extending from the years 1873 to 1903. The result of the inquiry is to show that the curves for the frequency at each of these regions have maxima at about the times of the sun-spot maxima and minima at about sun-spot minima, but underlying this variation one of half the period is apparent. In combining the results of all the three stations, the curve still shows the eleven-year variation with the change of shorter duration.

Dr. Steen suggests that similar observations covering other regions should be discussed to see if they exhibit similar changes.

Another reprint from the same "Hann Band" deals with the yearly air movement as determined by registering anemometers over some European stations, and is contributed by Dr. Felix M. Exner. The author discusses in the first instance wind observations made at Pola, Vienna, Potsdam, Zurich, Säntis, Bremen, Obir and Sonnblick.

His method of analysis is to calculate the resultant of the sixteen wind directions and to reduce them to north and west components. Thus winds from the west or east were considered as +W and −W, while those from the north or south were treated as +N and −N. The resulting west and north components were then determined for each year and expressed in units of hundreds of kilometres.

It is shown that according to the sign of the west component, with the exception of Pola, all the stations are under the influence of the general air circulation from the west. In the case of the north component, such a general result is not obtained. It is positive in Vienna, Zurich and on the Sonnblick, sometimes positive in Pola and on the Obir, but generally negative. Local causes are suggested as to the origin of some of these results. At Potsdam, Bremen and Säntis the north component is negative, and these are considered as good undisturbed stations.

The proportion of the north to the west component is generally less than 1 or 1 . . . so that the resulting wind direction is from the S.S.W. The author next investigates the atmospheric pressure values in relation to these variations of wind direction and velocity, and concludes that the yearly northern pressure gradients vary considerably, and that these changes harmonise in a satisfactory manner with those of the air movements. The paper is accompanied by numerous sets of curves showing the similarity of the variations discussed.

Prof. H. Hildebrand Hildebrandsson contributes an important article in the same "Hann Band" on the circulation of the upper layers of air above the maximum of the North Atlantic Ocean. Prof. Hildebrandsson refers to the recent important researches of Messrs. Rotch, Teisserenc de Bort, Hergesell, Clayton and Maurice, and finally, says that "our results concerning the general circulation of the atmosphere are verified by direct observations made by means of kite flying and free balloons."

The article is accompanied by two very instructive maps showing for summer and winter the mean direction of motion of the upper clouds in relation to the isobars. These charts bring out clearly the east-to-west motion throughout the year of the upper currents over the equator, and the west-to-east motion in the higher latitudes, indicating an enormous whirl of air round the pole.

In another reprint from the same source we have a discussion of two long series of evaporation measures made at the Kremsmunster Observatory; this discussion was undertaken by Prof. P. Franz Schwab, director of the observatory. The observations divide themselves naturally into two groups, the first series being commenced in 1821 and ending in 1845, while the second began in 1865, and is being continued to day.

Prof. Schwab in a series of tables brings together the monthly and yearly values, and treats the daily and annual variations at some length, comparing the latter with results obtained at numerous other stations.

Dietrich Reimer (Berlin, 1906) has published an excellent mean rainfall map of Germany, with explanatory notes which have been prepared by Prof. G. Hellmann. This map, which is on a scale of 1:1,800,000, shows the distribution of the mean yearly rainfall over the land from 3000 stations, the observations from which the values were derived extending from 1893 to 1902. To gain some idea of the distribution of these stations it may be stated that Prussia and the other North German States are represented by 2341 stations, Bavaria by 25, Saxony by 116, Wurttemberg by 90, Baden by 43, Hessen by 32, and Elsass-Lothringen by 70. Thus in North Germany there is one station for every 163 square kilometres, and one for every 205 square kilometres in South Germany. The map gives twelve different shades (ten in blue and two in yellow), and shows at a glance the geographical distribution over this part of Europe.

In the introduction to the meteorological report for the year 1903, published by the Survey Department, Finance Ministry, Cairo, we read that the meteorology series for Abbassia closes with the end of 1903, and that for Helwan begins from January 1, 1904. In this volume we have in the appendices the first instalment of a few discussions relating to the data collected at Abassia since it was started. These are quite brief, but the discussions will no doubt serve to indicate points for future study. Thus, for instance, the large differences in evaporation recorded at the observatory are well worth careful study, and they will no doubt be found to be closely associated with changes of other meteorological elements when a longer series of observations becomes available. The present report includes all the meteorological data collected at the observatory and various out-stations, together with daily readings of the various river gauges situated at different parts of the Nile. The reader's attention should, however, be

directed to the rather long list of errata for this volume given at the beginning of the report

In vol xx, part 1, of the Indian Meteorological Memoirs, we have the first instalment of what we hope will be a series of valuable contributions to the meteorology of the upper air in India

Up to the present time Indian meteorologists have been considerably hampered in dealing with the air circulation over India, as the only fact which existed from which they could form any idea of the air currents in the upper strata was the movement of clouds

A systematic investigation of the upper air began, however, last year, and the chief points of the inquiry in the first instance are to determine the distinctive features of the monsoon currents as regards their depths temperature and velocity gradients and humidity distributions

In the present memoir written by Mr F H Field, deputy meteorologist, and published under the direction of Dr G T Walker reference is naturally made more to the instruments employed and the methods of using them than to the observations recorded Advantage has naturally been taken of the experience of other workers in the field and the English, American, and German systems have all received careful study

The greatest height as yet reached is 1380 metres, and some details are given as to the records of the self-registering instruments employed during the flights made in August and September last when this elevation was reached

The importance of this method of investigation will at once be seen when it is noted that accurate measurements can be made of the elevation of the stratum of saturated air day by day Thus we read that "a nearly saturated stratum of air from the sea extended from the ground surface (about 10 metres above the sea) upwards to a level which rose from 500 metres on August 27 through 800 metres on August 28 to 1130 metres on August 31 From that day onward till September 9 its limiting height was not reached by the kite but probably exceeded 1000 metres its upper limit fell again by September 12 to 600 metres"

The reader is referred to the memoir itself for details regarding the apparatus used and the various interesting meteorological curves given relative to the numerous flights made

FURTHER RESULTS OF THE JESUP NORTH PACIFIC EXPEDITION

THE recently published memoirs of the Jesup North Pacific Expedition maintain the excellence both as to matter and illustration of the previous volumes Mr Swanton[1] gives an account of the religious ideas and social organisation of the Haida Indians, who, to the number of about 600, occupy the towns of Skidegate and Masset, Queen Charlotte Islands The whole Haida stock is divided into two "clans," the Raven clan and the Eagle clan the significance of the division being purely social Each is strictly exogamic, a Raven man being compelled to marry an Eagle woman, and an Eagle man a Raven woman while the children always belong to their mother's clan A man of the Raven clan was reckoned in that clan wherever he might go and the Ravens among whom he settled were his uncles, elder and younger brothers sisters and nephews The members of the opposite clan were frequently considered downright enemies "Even husbands and wives did not hesitate to betray each other to death in the interest of their own families At times it almost appears as if each marriage were an alliance between opposing tribes a man begetting offspring rather for his wife than for himself, and being inclined to see his real descendants rather in his sister's children than in his own" (p 62)

The Raven and the Eagle do not seem to have been deities or deified ancestors "A West Coast man said that the people sometimes left food for a raven on the beach, and, when it got near them told it to give them some thing' Another man however, said "they did not sacrifice to it or pray to it, because it stole too much as it was' And although Eagle was called "grandfather" by men of the Eagle clan, as Raven was called "grandfather" by the Ravens, this was not because either was regarded as a direct ancestor, "but because they had been prominent heroes of the mythical period, and belonged respectively to the Eagle and Raven clans"

The clans were divided into an indefinite number of "families," and the "family" is the fundamental unit in Haida society These usually take their names from towns or camping grounds, and are simply local groups The "family" was divided into households, and there were thus house chiefs, family chiefs, and town chiefs

The families had certain prerogatives which they guarded jealously, such as the right to use certain personal, house, and canoe names and the right to wear certain objects or representations of objects, and to carve them upon their houses or property 'These latter I have called 'crests' They were generally representations of animals, but trees, shells, and figures of objects used in daily life also occur They were originally obtained from some supernatural being or by purchase from another family" The author is wise in refraining from the use of the word *totem* in this connection for, as he justly remarks, "they have no proper totemic significance, their use being similar to that of the quarterings in heraldry, to mark the social position of the wearers", but the name "totem-pole" has crept in beneath the illustrations of the poles carved with crests, placed on front of the houses (Plates i–iii)

The author is of opinion that the 'crest system" was 'rooted in religion,' and that it may have developed from the personal manitou" (p 112)

The study of the Haida social organisation is of peculiar interest since it is possible to view the conflict actually going on between the purely maternal family organisation and the paternal property laws and the complexities resulting therefrom It is to be hoped that future observers will apply Dr Rivers's genealogical methods to the investigation of the sociology of these and other American tribes, as it would be sure to yield important results This method, however, was not published in time for Mr Swanton to utilise it

Turning to religious beliefs the Haida world is peopled with supernatural beings of the air, sea, and land, the sun is of comparative unimportance and the moon belongs to the Raven clan The chief of the Haida deities is Power-of-the-Shining-Heavens who gives "power" to all things, he is prayed to in sickness or sorrow and the clouds are his blankets Owing to the character of the country, the entanglement of land and sea, and the impenetrable nature of the interior, all communication must be by sea, and the supernatural beings of the sea have thus attained an exaggerated importance but a supernatural being can be destroyed "by cutting its body in two and throwing a whetstone between the severed portions In their endeavours to coalesce the two parts then grind themselves to nothing"

The shaman was "possessed" by a supernatural being, and became for the time being the supernatural being himself The calling was generally hereditary in the family, descending from maternal uncle to nephew but the youth had to qualify himself by training "Spirits would come and look around a village to find 'one who was clean' through whom they would act" To become "clean" a man had to abstain from food for a long time A spirit once looking through the smoke-hole of a house, saw a youth lying almost dead, "but he was so 'clean' that he looked transparent 'like glass' So the spirit entered him"

The volume, which is profusely illustrated deals also with secret societies and potlatches or the ceremonial giving away of property, and contains nearly 200 Haida stories

The third and last part of the volume of the Kwakiutl texts[1] collected by Dr Boas and Mr Hunt is now published These folk-tales form a mine of treasures for the folklorist and are especially valuable as giving unbiased and unconscious evidence concerning custom and belief

[1] Contributions to the Ethnology of the Haida By J R Swanton. Jesup North Pacific Expedition, vol v part i, 1905

[1] "Kwakiutl Texts' By Franz Boas and George Hunt Jesup North Pacific Expedition, vol iii part iii, 1905

Numerous songs are given, many being songs of cannibals The volume concludes with a *précis* of each tale The authors are to be congratulated on the termination of what must have been a laborious piece of work

The study of the religion and myths of the Koryak[1] is of particular interest, since these people are very little known, and they seem to have been successful in resisting the efforts of the Russians to convert them to Christianity, and to have preserved their primitive religion to a considerable extent

The Supreme Being occupies an important position in the religious life of the Koryak, but the conception of him is vague Nothing is known of his world-creating activity, except that he sent down Big Raven to our earth to establish order, and Big Raven is the founder of the world The One-on-High plays no active part in the myths which occupy more than one-half of the volume, these deal almost exclusively with the life, travels, adventures, and tricks of Big Raven, his children, and other relatives The value of this record is greatly increased by a comparison of the Koryak myths with Kamchadal, Chukchee, Yukaghir, Mongol-Turk, and American mythologies

Descriptions are given of the festivals and sacrifices, and customs at birth, death, and funerals many of the charms and sacred implements, and some of the ceremonies, are illustrated from photographs and drawings

A C Haddon

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge —The electors to the Isaac Newton studentships give notice that in accordance with the regulations an election to a studentship will be held in the Lent term 1907 These studentships are for the encouragement of study and research in astronomy (especially gravitational astronomy, but including other branches of astronomy and astronomical physics) and physical optics The studentship will be tenable for the term of three years from April 15, 1907 The emolument of the student will be 200*l* per annum, provided that the income of the fund is capable of bearing such charge Candidates for the studentship are invited to send in their applications to the Vice-Chancellor between January 16 and 26, 1907, together with testimonials and such other evidence as to their qualifications and their proposed course of study or research as they may think fit

The State medicine syndicate reports that it has held two examinations in tropical medicine and hygiene during the past year At the January examination six candidates presented themselves three of whom passed and received diplomas At the August examination eleven candidates presented themselves, of whom ten passed and received diplomas The syndicate proposes to contribute out of the funds in its hands the sum of 150*l* annually as part of the stipend of the reader in hygiene

Mr Ernest Gardner, M P has been appointed a member of the board of electors to the professorship of agriculture and Sir Walter Gilbey, Bart, an additional member of the board of agricultural studies

The following have been appointed examiners for the natural sciences tripos —physics, Mr C T R Wilson and Mr J A McClelland chemistry, Dr Fenton and Mr H B Baker (Oxford), mineralogy, Mr A Hutchinson and Mr H L Bowman (Oxford), geology Mr P Lake and Mr E J Garwood botany, Mr F F Blackman and Mr A G Tansley, zoology, Prof E W MacBride and Mr R C Punnett, physiology, Mr F G Hopkins and Dr T G Brodie (London), and human anatomy, Mr T Manners Smith and Dr A Robinson (Victoria)

The Mark Quested exhibition of 60*l* a year for three years ending Christmas, 1909 has been awarded to F A Potts, of Trinity Hall, assistant to the superintendent of the museum of zoology

The honorary degree of LL D has been conferred upon Sir W H Perkin F R S, by the Johns Hopkins University, Baltimore

A new building for the engineering department of the University of Pennsylvania was formally dedicated on October 19, and is said to be the largest and best equipped structure devoted to engineering education in the United States The cost, including equipment was 200,000*l*

The council of University College London, has received from the committee and subscribers of the Carey Foster Testimonial Fund the sum of 143*l* to be applied in the award of an annual prize in physics, to be known as the Carey Foster research prize This fund is the balance of that raised for the portrait of Dr Carey Foster which was presented to the council in July last

We learn from *Science* that the Georgia Legislature has appropriated 20,000*l* to erect and equip a building for the Agricultural College, and that the New York State College of Agriculture at Cornell University has received a gift of 6000*l* for the foundation of six agricultural scholarships Our contemporary also states that the University of Florida has been removed during the summer from its former position at Lake City to new grounds and new buildings at Gainsville, Fla The new grounds comprise a tract of five hundred acres just outside the city limits of Gainsville

In his report for 1906 on secondary education in Scotland, Dr J Struthers the secretary to the Scotch Education Department, devotes a section to the teaching of science After directing attention to the satisfactory progress made in the secondary schools of Scotland in developing a sound and well-considered course of experimental science, the secretary remarks on a common mistake in the practice of science teachers in allowing inadequate time for the discussion of experimental exercises As one of the inspectors reported to the Department, "unless frequent occasions are afforded for conference on class results, divergences, and conclusions, the work is apt to degenerate into a series of more or less isolated operations in which the pupils are found, not only lacking in their grasp of the subjects of study, but deficient in their knowledge of the units they are using and in their understanding of the constants they have determined" This failing is not confined to Scottish schools, and teachers would do well to take every precaution that the experiments do not degenerate into mere recipes unintelligently worked through by the pupils Unless the pupils acquire a comprehensive idea of the meaning of series of connected experiments they are obtaining little help in learning how to employ scientific methods

SOCIETIES AND ACADEMIES

London

Royal Society, June 21 —"Experimental Evidence of Ionic Migration in the Natural Diffusion of Acids and of Salts —Phenomena in the Diffusion of Electrolytes" By R G **Durrant.** Communicated by W A Shenstone, F R S

Conclusions —The results as given in the present paper appear to afford a considerable body of data tending to support the theory of Nernst and Planck

So far as the author is aware, the method of studying band boundaries has been almost entirely confined to experiments in which batteries have been employed, as in the work of Orme Masson and of Steele

The earlier experiments in jellies and the later experiments with silver nitrate and calcium chloride show that very fairly sharp bands are obtainable without batteries

The evidence goes to show that hydrogen ions move in advance of the diffusion front whereas other ions produce their various "effects" in the rear of the diffusion front

Entomological Society October 3 —Mr F Merrifield, president, in the chair —*Exhibitions* —Commander J J **Walker** A specimen of *Calosoma sycophanta* taken in Denny Wood, New Forest June 16 *Lygaeus equestris* L, found in the Isle of Sheppey on September 22 *Sitaris muralis* taken near Oxford in August by Mr A H Hamm varieties of *Vanessa urticae* *Argynnis adippe* *Lycaena icarus* ♂, and of an almost black form of *Strenia clathrata* occurring at Streatley Berks in August —all

taken this year.—G. T. **Porritt**: A series of *Abraxas grossulariata*, var. *varleyata*, bred this year from a pairing of the variety, all the brood being of the variety, none showing the least tendency to revert to the ordinary form.—C. P. **Pickett**: A gynandromorphous specimen of *Angerona prunaria* bred by him, and a ♂ specimen of *Fidonia atomaria*, caught at Folkestone, with six wings.—J. W. and H. **Campion**: Specimens of the rare dragon-fly *Sympetrum flaveolum*, taken near Epping in August last. It was suggested that these were part of a migration of the species such as occasionally takes place.—Dr. F. A. **Dixey**: Specimens of *Nychitona medusa*, Cram., *Pseudopontia paradoxa*, Feld., *Terias senegalensis*, Boisd., *Leuceronia pharis*, Boisd., and *I. argia*, Fabr. Although there does not exist any direct evidence that the members of the genus Nychitona are distasteful, their habits are such as to suggest this mode of protection, and there is little doubt that they have served as models for other insects.—H. St. J. **Donisthorpe**: Examples of *Dinarda pygmaea*, Wasm., with our other three species, *D. hagensi*, Wasm., *D. dentata*, Gr., and *D. maerkeli*, Kies., with their respective hosts.—Dr. N. **Joy**: Species of Coleoptera first recognised as British in 1906, a variety of *Lathrobium elongatum*, L., from South Devon, with entirely black elytra, and which he proposed to call var. *nigrum*, a curious dull aberration of *Apteropeda globosa*, Ill., *Heterothops nigra*, Kr., taken in moles' nests, and a species of Gnathoncus differing in certain characters from *G. rotundatus*, Kugel, and which occurs almost exclusively in birds' nests.—G. B. **Oliver**: A melanic ♀ of *Acidalia marginepunctata*, Goeze, and a melanic ♂ of *A. subsericeata*, Haw., both taken in North Cornwall this summer, together with the typical forms for comparison, also a dark aberration of *Coenonympha pamphilus*, Linn., taken in the same district.—**President**: A series of *Selenia bilunaria*, illustrating the remarkable angulation of the wings in these examples.—*Papers*.—The formation of a new nest by *Lasius niger*, the common black ant: H. W. **Southcombe**.—Some notes on the dominant Müllerian group of butterflies from the Potaro River district of British Guiana: W. J. **Kaye**.—A contribution to the classification of the coleopterous family Passalidæ: G. J. **Arrow**.

October 17.—Mr. F. Merrifield, president, in the chair.—*Exhibitions*.—H. St. J. **Donisthorpe**: Living specimens of the beetle *Mononychus pseudacori* found in plants of *Iris foetidissima* found at Niton, Isle of Wight.—A. H. **Jones**: A collection of butterflies from Arosa, Switzerland, at 6000 feet, and varieties of *Melanargia galatea* and *Argynnis niobe*, ♀, taken on the Splugen Pass in July, also specimens from other localities for comparison.—W. J. **Kaye**: A fine example of the remarkable moth *Dracenta rusina*, Druce, from Trinidad. The species bears a wonderful resemblance to a decayed dead leaf, the patches on the wings suggesting the work of some leaf-mining insect.—E. M. **Dadd** showed a number of Noctuids common to the British Isles and Germany, and directed attention to the constant differences between the prevalent forms occurring in England and the prevailing forms of the same species on the Continent.—Dr. F. A. **Dixey**: Specimens of *Ixias baliensis*, Fruhst., and *Huphina nerissa*, Fabr., remarking that the association between the two species must necessarily be Müllerian, and not Batesian.—S. A. **Neave**: A number of Lepidoptera selected from the collection made by him in N.E. Rhodesia, in 1904 and 1905, comprising the following rare and remarkable species:—*Melanitis libya*, Distant, *Liptena homeyeri*, Dewitz, *Pentila peucetia*, Hew., *Catochrysops gigantea*, Trim., *Crenis pechueli*, Dewitz, and *Crenis rosa*, Hew., which are evidently two distinct species, and *Crenidomimas concordia*, Hopff., the mimic of the last two species. Also two remarkable species of the genus Aphnæus—including the female, so rarely taken in this genus—*Acraea natalica*, Boisd., and *Acraea anemosa*, Hew., with two remarkable moths showing a close mimetic resemblance to them. The exhibitor further stated that his collection should prove interesting as regards seasonal forms, especially in the Acræinæ and Pierinæ, of which he showed additional examples.

Royal Microscopical Society, October 17.—Mr. A. N. Disney, vice-president, in the chair.—*Cornuvia serpula*, a species of Mycetozoa new to Britain: J. M. **Coon**. For the first time a complete description was given of all the stages of this organism, previous descriptions being limited to the mature plasmodicarp and its contents.

Physical Society, October 26.—Prof. J. Perry, F.R.S., president, in the chair.—The strength and behaviour of ductile materials under combined stress: W. A. **Scoble**. In former tests of materials under combined stress either the ultimate strength or elastic limit stress has been considered, and the tensions have been applied either directly, or by internal pressure in the case of thin tubes, so that the distribution of stress was approximately uniform. The present experiments were made on bars ¾-inch diameter, subjected to bending and twisting to reproduce the irregular distribution of stress occurring in practice. The yield-point was selected as the criterion of strength, but it is open to more than one specification. Here the stress corresponding to the first sign of yield was not taken, but that given by the intersection of the two parts of the stress-strain diagram corresponding to perfect elasticity and complete yield, so that the intermediate state was neglected. The critical bending moment was found to be greater than the yield torque, 2660 and 2400 lbs. ins., and plotting the corresponding bending and twisting moments the ellipse gave the closest approximation to the results.—The behaviour of iron under weak periodic magnetising forces: J. M. **Baldwin**. The behaviour of iron in strong alternating fields has been studied by many observers, and the induction in iron when placed in both strong and weak fields has been thoroughly examined by static methods, but up to the present no results have been published of the induction in weak alternating fields. The author has now, however, succeeded, by means of Lyle's wave-tracer (for description of which see *Phil. Mag.*, vol. vi., p. 549), in examining the induction in periodically varying fields down to extremely low amplitudes. The principal points brought out are as follows:—(1) the permeability satisfies a linear law through a considerable range for weak fields, diminishing to a minimum about 150 as the amplitude of the field diminishes; (2) as the field diminishes the difference in phase between the induction and the magnetising force tends to disappear; and (3) at the same time the hysteresis losses become very small; (4) frequency at these low values of the field has practically no influence on the results obtained.—Fluorescence and magnetic rotation spectra of sodium vapour and their analysis: Prof. R. W. **Wood**. After recapitulating the descriptions of the experimental arrangements given in previous papers, the author describes the work done during the present year in photographing magnetic rotation and fluorescent spectra. A 12-feet grating, a specially constructed three-prism spectrograph, and a monochromatic illuminator were used.

Challenger Society, October 31.—Prof. d'A. W. Thompson in the chair.—Preliminary note on a method of detecting successive moults of the same species among Crustacea: Dr. **Fowler**. The uncertainty of connecting together in series the successive stages of larvæ captured in tow-net hauls is great, especially if the general form and appendages differ at different moults. Brooks noticed twenty years ago a curious numerical relation between the lengths of four specimens of stomatopod larvæ, which appears to be capable of expansion into a regular law, and if the larvæ captured be sorted at first by general morphological similarity and by constant association in the same hauls, it seems probable that this law will give the key to their relationship. The author had measured and sexed more than 400 specimens of *Conchoecia subarcuata*, Claus = *macrocheira*, Müller. The males and females each fell into three groups when arranged by lengths, when the frequency of the lengths occurring in each group was plotted each formed a small "curve of frequency," and the mean length of each group when multiplied by a certain factor (found experimentally) yielded the mean of the next highest group, the extremes, similarly multiplied, yielded, approximately, the extremes of the next highest curve. The factor is different for males and for females, and seems to be an expression of

the percentage of its total length by which the animal increases between two moults, this is apparently constant for every moult This law is also very clearly observable when applied to the measurements of lobster larvæ recorded by Herrick—Three graphic methods of recording temperature observations in use in the section of the International Investigations of the North Sea conducted by the Scottish Fishery Board Prof d'A **Thompson.** One method recorded the surface temperatures at any date and any position along a given line, another the temperature at any date and depth at a given position, the third showed the daily sequence of temperatures for the year at any given position in the form of sine curves

Linnean Society, November 1—Prof W A Herdman, F R S, president, in the chair—The structure of bamboo leaves Sir Dietrich **Brandis.** While the leaves of other grasses exhibit a great variety of structure, those of bamboos are exceedingly uniform In bud they are always convolute, they all have in the upper epidermis, alternating with the longitudinal nerves, bands of large bulliform cells known as motor-cells In most species these motor-cells are filled, entirely or partially, with solid bodies of silica Between the bands of bulliform cells and the longitudinal nerves, bamboos (with one exception so far as known, *Chusquea pinifolia*, of south-east Brazil) have large apparent cavities, which are completely filled by large flat thin-walled cells, lying one over the other, like the leaves of a book This tissue is entirely different from that which in a young state, fills the cavities in the leaves of *Glyceria aquatica*, *G fluitans*, and other aquatic grasses The species placed by Dr Stapf in "Flora Capensis" in the new tribe Phareæ have, so far as known, leaves with a structure similar to bamboo—Crustacea from the Inland Sea of Japan Dr J G **De Man** Thirty-nine species were fully described, and ambiguities in previous authors cleared up—The systematic position of *Hectorella caespitosa*, Hook f Prof A J **Ewart** This plant has been regarded as belonging to the Portulaceæ, but the author suggested it might be transferred to the Caryophyllaceæ

Mathematical Society, November 8—Annual general meeting—Prof A R Forsyth president, in the chair—Partial differential equations some criticisms and some suggestions Presidential address by Prof **Forsyth** The address dealt chiefly with the present state of the methods of practical integration, a number of exceptional cases in regard either to method or classification, were pointed out, and various gaps in the theory were indicated Some suggestions as to hopeful lines of advance were made—Harmonic expansions of functions of two variables Prof A C **Dixon** A function of two real variables having a considerable degree of generality, is expanded in a double series each term of which is the product of two functions containing the two variables separately, and also containing parameters which differ from term to term of the series The series is transformed into a multiple integral The series that are founded on this expansion are found to be equally complete with double Fourier's series—The inversion of a definite integral H **Bateman** The paper contains a classification of integral equations of the first kind, two practical methods of proceeding to a solution and a number of illustrative examples—Partial differential coefficients and repeated limits in general Dr E W **Hobson.** Among the matters treated is the formulation of the most general conditions in which the equation

$$\frac{\partial}{\partial x}\left(\frac{\partial u}{\partial y}\right)=\frac{\partial}{\partial y}\left(\frac{\partial u}{\partial x}\right)$$

holds good—Bäcklund's transformation and the partial differential equation $s=F(x, y, z)$ J E **Campbell** The form of differential equation in the title includes the differential equation of all pseudospheres, or surfaces of constant negative curvature In this case the equation admits of being transformed into itself by a transformation due to Bäcklund The transformation succeeds also in one other case—Subgroups of a finite Abelian group H **Hilton**—The general solution of Laplace's equation in n dimensions G N **Watson.**

Manchester

Literary and Philosophical Society, October 26—Sir William H Bailey, president, in the chair—A development of the atomic theory which correlates chemical and crystalline structure and leads to a demonstration of the nature of valency Prof W J **Pope** and W **Barlow**

October 30—Mr Charles Bailey in the chair—(1) A journey to North-East Rhodesia during 1904 and 1905, (2) a collection of birds from North East Rhodesia S A **Neave**

Paris

Academy of Sciences, November 5—M H Poincaré in the chair—The alcoholysis of fatty bodies A **Haller.** The hydrolysis of fatty substances by an aqueous solution of various acids is well known The author has found that if the acids are employed in alcoholic instead of aqueous solution the glycerol is split off as before, but the alkyl ester of the acid is formed, and hence the process may be fitly called alcoholysis All fatty bodies whatever their constitution or consistency, undergo this change with more or less facility Full details are given of the methods used in carrying out this reaction, which has been applied to a large number of glycerides Owing to the low temperature at which the reaction can be completed, the replacement of water by alcohol possesses certain advantages—The transformation of volcanic rocks into phosphate of alumina under the influence of products of physiological origin A **Lacroix** The change takes place under the influence of the excrement of sea birds—The seeds and flowers of Callipteris M **Grand'Eury** The frequent presence, along with Callipteris, in the neighbourhood of Autun, of seeds catalogued thirty years ago under the name of *Carpolithes variabilis*, found with an intimate mixture of the same seeds with *Call conferta* in the coal deposits of Bert, formed exclusively of this fossil, led the author to the view that these belonged to the same plants In the present paper an account is given of a study of the flora of the Autun boghead which confirms this view—The perturbations of Vesta depending on the product of the masses of Jupiter and Mars M **Leveau**—Certain linear groups Léon **Autonne**—The potentials of an attracting volume the density of which satisfies the equation of Laplace A **Korn**—Certain kathode rays P **Villard** Some remarks on the nature of the non-deviable rays observed in a Crookes's bulb by J J Thomson—The establishment of an exclusive correspondence independent of syntonisation, between a transmitting post and one of the receiving posts of a wireless telemechanical installation Edouard **Branly**—The conditions of precipitation and re-dissolution of metallic sulphides H **Baubigny** Remarks on a paper by M G Bruni and Padoa, the author referring to papers by himself on the same subject published in 1882 and 1889—The gases observed in the attack of tantalite by potash C **Chabrié** and F **Levallois** Experiments on tantalite and the corresponding ferrous titanate show that the hydrogen observed in the reaction with potash is not present in the mineral, but is due to a chemical reaction between ferrous oxide and the alkali—Contribution to the study of selenium Œchsner **de Coninck** By the reduction of selenious oxide by glucose, an amorphous brick-red selenium is produced This dissolves gradually in concentrated sulphuric acid forming $SeSO_3$ This latter substance in contact with water deposits a new stable variety of selenium, the properties of which are detailed—The chlorination of paraldehyde and on butyric chloral P **Freundler**—Phenyl migration the structure of the intermediate compounds M **Tiffeneau**—Study of the constitutional formulæ of some dimethylanthracenes James **Lavaux**—The toxicity of some rare earths their action on various fermentations Alexandre **Hébert** The sulphates of thorium cerium lanthanum, and zirconium possess certain toxic powers Experiments on frogs, fish, the seeds of plants, Aspergillus yeast, diastase and emulsin are described—An albumin extracted from the eggs of fish comparison with the vitelline from hens eggs L **Hugounenq** By hydrolysis with dilute sulphuric acid the albumin from the egg of *Clupea Harengus* (clupeovine) gave arginine histidine lysine aminovaleric acid tyrosine leucine, alanine serine phenylalanine and aspartic acid These correspond closely

with the products of hydrolysis of egg-albumin, but the ratios in which the various substances are produced differ in the two cases —The liquid crystals of ammonium oleate Fred **Wallerant.**—The indirect actions of electricity on germination Pierre **Lesage** —The histological structure and development of the osseous tissue in ectromelian monsters J **Salmon** —Cytology and pathogeny of spermatic cysts J **Sabrazès.**—The development of polygenesis and the theory of concrescence Jan **Tur** —The dislocations of the edge of the Central Plateau between Voulte and Vans (Ardèche) Émile **Haug.**—The Jurassic strata in Greece Carl **Renz.**—The archæan substratum of the globe and the mechanism of geodynamical actions E **Jourdy.**—The circumzenithal rainbow Louis **Besson**

NEW SOUTH WALES

Linnean Society, September 26 —Mr T S eel, president, in the chair —The sound (and lake) basins of New Zealand and the cañons of Eastern Australia in their bearing on the theory of the peneplain E C **Andrews.** An attempt from an examination of Eastern Australian and New Zealand geographical types, to prove Prof Davis's contention that the greater number of plateaus of erosion are elevated *peneplains* formed at or near sea-level Streams speedily cut profound cañons, the bases of which, even prior to the passing away of the individuality of the central plateau, approximate closely to the level of the main water body into which they are discharging Large floods determine these channel grades, the normal stream being functional in aggrading the holes formed *below* main or temporary base-level by the storm waters The lake and sound basins of New Zealand represent holes ploughed out below base-level by swiftly converging glaciers and are analogous to the deep flood holes found in river beds —A correlation of contour, climate, and coal a contribution to the physiography of New South Wales T Griffith **Taylor.** It is submitted that the rivers of the Murray Darling system show evidence of the influence of Ferrel's law on their courses The gap in the Great Divide situated near Cassilis is due to the shifting of the Divide by the Goulburn River The cutting action of this river has been determined by the lower "coefficient of resistance" of the Permo-Carboniferous Coal-measures The relation of the temperature lines and of the lines of rainfall is shown to be influenced by this Geocol —The stinging property of the giant nettle-tree (*Laportea gigas* Wedd) Dr J M **Petrie** The physiological action is shown to be due to the free acid existing in a concentrated form in the hairs which are hollow siliceous tubes, and it differs from the sting of the common nettle only in degree Laportea contains ninety times more free acid than the common nettle —A striking example of river-capture in the coastal districts of New South Wales Dr W G **Woolnough** and T Griffith **Taylor** The authors have examined the topographical relations of the bend in the Shoalhaven River near Marulan Field evidence shows the existence of a fairly well-defined ancient river-channel connecting the Shoalhaven and Wollondilly watersheds Along this line are well-defined coarse river-gravels derived from the southward The structure of this former river-channel is described It is pointed out that other instances of capture of Wollondilly water by branches of the Shoalhaven are imminent for instance, in the neighbourhood of Bundanoon —Supplement to the "Revision of the Cicindelidæ of Australia" Dr T G **Sloane.**—Descriptions of new species of Lomaptera (Coleoptera Scarabæidæ, subfamily Cetonides) A M **Lea** Two species are described, from specimens obtained by Mr H Hacker at Coen, N Q, a district which appears to be rich in showy beetles especially in Cetonids and Longicorns

A BIBLIOGRAPHY OF PHILOSOPHY

Dictionary of Philosophy and Psychology Edited by Prof. J Mark Baldwin Vol iii Two parts Part i, pp xxiv+542, part ii, pp vi+543-1192 (New York: The Macmillan Company, London Macmillan and Co, Ltd, 1905) Price 42s net

WITH the publication of this "Bibliography of Philosophy, Psychology, and Cognate Subjects," Prof Baldwin's great enterprise comes to an end, and he and his collaborators are to be congratulated on the successful completion of a work that will be indispensable to the teacher and student of philosophy The compiler of this latest volume, Dr Benjamin Rand, of Harvard, will in particular receive the thanks of those who hitherto have painfully had to make their own bibliographies from *Jahresberichte* and various popular indexes and who in the fulness of their ignorance have not been able to neglect even the humble catalogue of the Leipzig bookseller

The work does not profess to give references to books and articles that have appeared since 1902, but up to that date it seems to be very complete, at any rate a first perusal does not reveal very startling omissions Psychology is, of course, one of the strongest features of the Dictionary, and of this present volume, of which it occupies 280 pages, and the editor points out in a prefatory note that the annual volumes of the Psychological Index from 1902 may be regarded as a supplement of this Dictionary Accordingly, those who possess this Dictionary and secure the index each year from 1902 "will have for Psychology an exhaustive Bibliography, and for the other topics of this volume one that is selective and fairly adequate, continuing indefinitely into the future"

The scheme of the volume seems to cover all the ground, and the headings are well arranged The first part is occupied with a few pages containing a bibliography of bibliographies, then about fifty pages of general works on the history of philosophy, then come about 500 pages on philosophers, their works, and works upon them We note that Aristotle has twenty-four pages assigned to him, Darwin five, Kant thirty-four, and Plato nineteen Naturally there has been some hesitation in selecting for this columbarium any but the most prominent of living philosophers, Wundt is there, and Bain (though he was alive in 1902), but not Mr F H Bradley or Mr Shadworth Hodgson Those, however, who have not attained a place beside Plato and Aristotle, and some six hundred of the majestic dead, have tardy justice done them under the later head "Systematic Philosophy Systems and Essays" Under systematic philosophy we have such further headings as atomism, evolution (only eight pages!), materialism, positivism, teleology, and the like Then come the sections of logic, æsthetics, philosophy of religion ethics, and psychology The biologist and the student of the physical side of mental processes will note that to the brain and its functions are given fifteen pages, to heredity two to the nervous system ten, to sensation and the senses about thirty-eight The arrangement under each heading is, of course alphabetical according to the names of the writers, which are generally printed in heavy type The main references to epoch-making works—and to some not epoch-making—are followed immediately by a note of the important reviews that greeted their appearance One must heartily commend the fulness with which, *e g* under atomism, we have the references to Aristotle's discussions of the topic Phys II, 4 196 a 25, III, 4 203 a 22 But perhaps in dealing with important Greek and Latin authors an attempt should have been made to distinguish translations and commentaries

Without being captious, however, we must complain that the number of misprints is a little too large It is irritating to have to inquire whether some new writer or thinker has suddenly appeared whose name differs from someone of comparative fame only in one of the initial letters H for A, or G for S or C for F Such misprints must occur, but woe to the editor or proof-reader of a bibliography in which misprints attain more than a certain proportion

THE ROMANCE OF THE EARTH AND MAN

The Human Epic The Prehistoric Story of Mankind By John Frederick Rowbotham Pp 214 (London Gay and Bird, n d)

THE author of this remarkable publication, like the Mayor of Coquerico in "Genevieve de Brabant," is by no means averse to blowing his own trumpet, accordingly he announces to the world at large on the title-page of his work, that it is "the twelfth Epic Poem of the world", he also modestly states that he is "The Homer of Modern Times" Such courage deserves our applause, even if we fail to recognise the modern representative of Greek poetry in Mr Rowbotham

The author begins with the evolution of the earth and the origin of life and strives to show the changes undergone by the inorganic world and the gradual appearance of lowly marine beings in the Cambrian and Silurian seas Of poetic fancies the author nothing lacks, but of natural history lore his stock is meagre —

"Much fear I him who armed with claws and quills
Steals stealthily along the weedy mire
I dread the shape who bears the bristling gills
Which seem with rage and venom to respire
But chiefly do I fear the lobster dire
Four claws he wears, his quarry to assail,
Two spears he brandishes to wreak his ire,
Invulnerable gleams his quilted mail
O'er such stupendous foe nought living can prevail"
(p 27, v 35)

We are quite at a loss to fit the author's description with any Silurian, or, indeed, any other fossil arthropod!

We are next favoured with a view of the Old Red Sandstone period and its armoured fishes, then of the "Age of Trees"—"One mighty Sunderbund earth's surface seemed which with evaporating moisture steamed," but though we surmise this to be a view

of the Coal period, the author does not hint at any definite geological fact, save that mosses and *bull-rushes* (query Equisetaceæ) became gigantic trees After upheavals in the Permian period we arrive at the "Age of Monsters," by which the author means the Ichthyosaurus and the Plesiosaurus, which (after Blake's picture in Hawkins's "Sea Dragons") have a mighty battle, the Ichthyosaurus coming off conqueror We are next *introduced to* "The Giant Newt" (probably the Pariasaurus?), then to the Atlantosaurus, moving with his head in the clouds! Pages of grandiloquent poetry, after the pattern of Pope's translation of Homer's Iliad, are devoted to an impossible battle between herds of armed herbivorous Dinosaurs and armies of carnivorous ones, the author apparently being unaware that the latter were extremely few in number compared with the former, just as the herbivorous mammals were as a thousand to one carnivore on the African plains before "man the destroyer" came upon the scene with his "shooting-iron"

> ' And howls of anguish and of beasts dismayed
> Strike on the air In crowded cohort stand
> The monsters of the plains, begirt on every hand
> Their roaring foes less huge, but of a shape
> Obscene and foul beyond a parallel,
> Rush on to decimate with jaws agape
> The remnants thus enclosed These slowly fell" (p. 58, vv 40, 41)

In canto the tenth the author gives us "A Day with an Iguanodon," and with the late Mr J L Toole we are inclined to exclaim, "oh! what a day we are having"

> "In ten enormous strides he fared a mile
> Towering above the tree tops as he strode
> He soon was in his den amid the ferns bestowed" (p 69, v 31)

In the eleventh canto we reach the Tertiary period, and have the first glimpse of ape-like man reflecting on the scene from a tree overlooking a pool at which the Dinotherium, Palæotherium, Anoplotherium, Mastodon, Dinoceras, Megatherium, and Mylodon (as was their habit!) came down to slake their afternoon thirst The author is so pleased with this idea that he repeats on pp 76, 77, vv 32 and 38 and p 82 v 15, the same scene

He goes on (in canto thirteen) to describe "The Earthly Paradise," and on pp 85, 86, gives an unlovely picture of humanity in its early stage, but on p 87, vv 27-34, evolves from the baser herd a superior pair endowed with finer instincts, but on p 89, v 35 he admits —

> "Yet were they both but brutish beasts amid
> That garden of delights, that Paradise, ' &c
> The male on lank and shaggy shanks upreared,
> Whose breast and back unsightly bristles drape
> Whose monstrous snout protuberant appeared,
> Whose brutish jaws seemed evermore to gape
> With teeth and tusks of dire revolting shape" (p 89, v 36)

The flood follows, then cave-dwellers are depicted, and the use made of stones as weapons, of skins as clothing, and the discovery of fire making, the sling, the spear, bow and arrow, and so on

The whole material is woven up into a poetic and exaggerated form which to our way of thinking, renders it highly unsatisfactory Kitchen-middens, lake-dwellings, the continent of Atlantis, the capture of the first horse, the potter's art, the origin of ornaments, of music, singing and dancing, are introduced Then legends are touched upon, the domestication of the dog, the wandering minstrel, and, lastly, a legend of the "Ice age" into which we cannot follow the learned author Mr Rowbotham's legendary lore and his talent for versification may be admirable, but his geology and palæozoology are extremely shady, and we do not recommend him as a guide to follow in his reconstructions of the past history of the earth or of prehistoric man

MATHEMATICS FOR SCHOOLS

(1) *Elementary Geometry based on Euclid's Elements* By F Purser Pp vii+121 (Dublin Hodges, Figgis and Co, Ltd, London Longmans, Green and Co, 1906)

(2) *Geometry, Theoretical and Practical* Part 1 By W P Workman and A G Cracknell Pp x+355 (London University Tutorial Press, Ltd, 1906) Price 3s 6d

(3) *Elementary Geometry* Books vi and vii By W M Baker and A A Bourne Pp 390-477 (London G Bell and Sons, 1906) Price 1s 6d

(4) *A Shilling Arithmetic* By S L Loney and L W Grenville Pp 186+xxiv (London Macmillan and Co, Ltd, 1906) Price, with answers, 1s 6d

(5) *Junior Arithmetic with Answers* By W G Borchardt Pp viii+221+xl (London Rivingtons, 1906) Price 2s

(6) *A Junior Arithmetic* By C Pendlebury, assisted by F E Robinson Pp xii+204 (London G Bell and Sons, 1906) Price 1s 6d

(7) *A Preliminary Course in Differential and Integral Calculus* By A H Angus Pp vi+108 (London Longmans, Green and Co, 1906) Price 2s 6d

(8) *A College Algebra* By Prof H B Fine Pp viii+595 (London and Boston Ginn and Co, n d) Price 6s 6d

(9) *A New Trigonometry for Beginners* By R F D'Arcy Pp viii+84 (London Methuen and Co, n d) Price 2s 6d

(10) *Elementary Descriptive Geometry* By C H McLeod Pp ix+118 (New York John Wiley and Sons, London Chapman and Hall, Ltd, 1905) Price 6s 6d net

(1) IN Mr Purser's "Geometry" the subject-matter corresponds essentially with that of the first six books of Euclid, and the treatment is on similar lines, but the propositions are differently arranged, and are grouped, with the object of showing the reasons for the sequence adopted Euclid's definitions of parallels and proportion are adhered to, though the defective statement of the former on p 17 must be due to an oversight No exercises are provided, and teachers will find little to induce them to adopt the book in their classes

(2) In the "Geometry" by Messrs Workman and Cracknell we have a very full treatment of angles,

parallels, triangles, parallelograms, and circles, with areas, loci, and symmetrical figures. There is a short introductory course of experimental geometry, followed by a preliminary chapter on the "science of geometry," in which fundamental concepts, axioms, and deductive processes are discussed. Thus prepared, practical work and logical development proceed together. There are exercises in abundance of all types, theoretical, constructive and numerical, the answers to the latter being given. There is a useful index of terms, and a collected list of propositions very convenient for reference. The book should prove of great value to teachers and pupils alike, and seems altogether good.

(3) The new volume by Messrs. Baker and Bourne deals with the geometry of three-dimensional space. Book vi. corresponds with Euclid xi., and Book vii. gives the mensuration of the simple geometrical solids. The high standard of the authors' previous work is maintained. The treatment is clear and concise, the printing is excellent, and useful sets of exercises are provided for class work.

(4) The "Shilling Arithmetic" by Messrs. Loney and Grenville is a handy little volume intended more especially for use in secondary schools, and consisting mainly of a very large collection of graduated examples with explanatory notes. Physical as well as commercial arithmetic is represented, though examples of the latter type predominate. Answers are given at the end, and altogether the book is very suitable for its purpose.

(5) Mr. Borchardt's "Junior Arithmetic" is very like the one just noticed, but more use is made of graphs, the commercial type of exercise is less prominent, and the treatment follows more closely the scheme of the committee of the Mathematical Association. A special feature of the book is a set of 385 examples arranged as a graduated set of fifty-five test papers covering the whole subject. The course will form a good preparation for the Oxford and Cambridge locals, the London matriculation, and similar examinations.

(6) The "Junior Arithmetic" by Messrs. Pendlebury and Robinson is very similar in character to the two just mentioned, and is well suited for use under similar conditions. In all three there are too many exercises of the kind "If 120 men can build a house 60 feet high in 15 days, how many men will it take to build one 55 feet high in 10 days?" But the teacher can delete these and still have ample choice. The book can be obtained with or without answers.

(7) Many students rightly wish to acquire an elementary working knowledge of the calculus at a comparatively early stage. By such the preliminary course of Mr. Angus will be appreciated. The author confines himself to the algebraical, trigonometrical, and exponential functions, and has thus space available for ample illustration. There seems to be a want of clearness in the author's notion of a rate, for instance, on p. 27, where in the expression $dV/dD = \pi D^2/2$, relating to a sphere, V denoting volume, he puts dV equal to 7.5 *cubic inches per second*, a statement which must perplex a thoughtful student. However the book is a good one, and can be recommended to beginners who have some knowledge of squared paper work.

(8) The "College Algebra" by Mr. Fine is a very masterly and fascinating treatment of the subject, whether from the standpoint of logical completeness or of practical computation. The book is divided into two parts, the first and smaller of which establishes the fundamental laws of operation for numbers, rational and irrational, imaginary and complex, the discussion being based "on the notion of cardinal number and the notion of order, as exhibited in the first instance in the natural scale 1, 2, 3. . . ." The second and main part of the work deals most thoroughly with the successive developments, and carries the subject so far as to include, in the later portions, the theory and solution of cubic and biquadratic equations, determinants, the binomial, exponential, and logarithmic series, the properties of continuous functions, &c. The volume is beautifully printed, and whether adopted or not as a text-book in this country, so excellent a treatise should be found in the library of every teacher of mathematics.

(9) As a first course of trigonometry for beginners the elementary text-book of Mr. D'Arcy is well conceived, the work being closely associated with quantitative practical geometry, and being carried only so far as problems on heights and distances and the solution of triangles, complex trigonometrical transformations being wisely absent. At the same time the idea of the book is not well carried out in detail. The style is unattractive, and the illustrations are not very illuminating. The figures are badly printed and sometimes are scarcely legible. More attention might well have been given to the solution of triangles by means of right-angled triangles, and it seems a mistake to have omitted to include the four-figure tables in the text. The book is designed for candidates taking the Cambridge previous or the Cambridge general examination, and test papers at the end contain many questions selected from these examination papers.

(10) The "Descriptive Geometry" by Mr. McLeod is intended as a minimum course for engineering students. It deals in a simple and straightforward manner with elementary problems on points, lines, and planes, polyhedra, curved surfaces and tangent planes, including several skew surfaces, sections, envelopes and developments, trimetric projections, and shadows.

PHOTOGRAPHIC TOPICS

The Complete Photographer. By R. Child Bayley. Pp. xv+410. (London: Methuen and Co., n.d.) Price 10s. 6d. net.

AFTER having read this volume, the question that naturally presents itself to the reviewer is to what class of readers will it appeal? The author, in his preface, states that he has made no attempt to compete with the many books on photography that have already been published, whether scientific treatises upon the principles underlying the practice or manuals of practical instruction. He states, further

and quite correctly, that the formulæ given are very few, and that "it is their application to photography that has formed his topic" The student, therefore, will not always find here the practical instructions that he needs, sometimes, in fact, quite otherwise If, for example, he wishes to varnish a negative, and turns to the page indicated in the index, he reads that "the modern dry-plate worker finds the result of the first operation is to send a stream of varnish up his arm, of the second to make a pool of it on the floor and of the third to cement a number of dust particles to the surface of the negative, and, possibly, to set the whole of the varnish alight" As the author considers that there is no reason why an amateur photographer should varnish his negatives, he does not help him to do it

It is essentially a personal treatise Those subjects that commend themselves to the author he discourses on at length, and sometimes in much detail, others he merely refers to, and in most cases he expresses his own opinions in very decisive terms There are some opinions with which we do not agree, but the volume is easy reading, and if at any time we begin to get annoyed with the expression of views that we are inclined to condemn, a page or two forward is sure to bring us face to face with a charming picture that cannot but please, though it has no connection whatever with the text, except that it is a photograph Photography pure and simple is dealt with in nineteen chapters, then follow chapters on "Dodging and 'Faking,'" landscape architectural work, and portraiture, "Pictorial Photography," "Exhibitions and Societies" and a few pages on photomechanical work

We notice only a few errors, and as most of them are not obvious slips it may be worth while pointing them out Sodium hypochlorite is included among "hypo eliminators", of "very doubtful efficacy" As it is supposed readily to oxidise the thiosulphate to sulphate, experimental evidence should be adduced before its efficacy is doubted The statement at p 157 that a "focal-plane shutter allows the whole of the light which passes through the lens, to fall on any part of the plate which it uncovers" certainly needs amending A few lines lower, a roller blind shutter with an opening that is equal in length to twice the diameter of the lens, and travelling at a uniform rate is stated to leave "the lens fully open for exactly half the time during which it is uncovered at all" For this result the length of the opening should be three times the lens diameter The author must have been misinformed as to the "Linked Ring," for he states that it came into existence by reason of a "personal squabble" in the Royal Photographic Society As he goes on to say that "signs are not wanting that the 'Linked Ring' in its present form has outlived its utility," his attitude appears to be far from friendly towards this Society, but it might have been better if he had refrained from giving his opinion in this place To those who know enough about photography to appreciate it, and there must be a very large number of persons so qualified, the volume will prove both entertaining and instructive

POPULAR NATURAL HISTORY.

(1) *Nature's Story of the Year* By C A. Witchell. Pp xii+276 (London T Fisher Unwin, 1906.) Price 2*s*

(2) *Creatures of the Night* By A W Rees Pp xix+448 (London John Murray, 1905.) Price 6*s* net

(3) *The Life Story of a Fox* By J C Tregarthen Pp viii+224 (London Adam and Charles Black, 1906) Price 6*s*

(4) *The Romance of Animal Arts and Crafts* By Dr H Coupin and John Lea Pp 356 (London Seeley and Co, Ltd, 1907) Price 5*s*

(5) *Our School Out of Doors* By the Hon M Cordelia Leigh Pp xii+141 (London T Fisher Unwin) Price 2*s*

(1) MR WITCHELL is great as an observer He has studied the ways of sticklebacks With still more patience and insight he has watched the courtship of willow-wrens and of skylarks He has much to say about the habits of swifts that is worth reading He is at his best when he is writing about birds, though such an affectionate observer has, of course, the defect of his virtue He sympathises so keenly with his favourites that he reads into their lives a good deal which may or may not be there They are to him beings full of almost human thoughts and passions But whether we go along with him in his inferences or not, he makes it plain that there is a great deal in nature that most of us fail to notice We must regret that he feels so much contempt for comparative anatomy and classification, things of some importance, though Mr Witchell is not alive to it But chiefly we must regret that our author sometimes aims without success at a very high-flown style of writing On p 76 is a notable example In the first chapter he is a philosopher rather than an observer, and for this *rôle* he is not so well qualified But if his readers go on with the book they will find themselves rewarded

(2) Mr Rees's "Creatures of the Night" is a very readable book It is written in good style Though not so exciting as some books of animal biography, it has an air of genuineness and reality Lutra is a real she-otter, Brock is a real badger, and we get interested in Brighteyes the water-vole There is, of course, a tendency to make the heroes of these animal stories too human, but that is inevitable in literature of the kind

(3) Mr Tregarthen's is a book of the same class, but with this difference, that the hero, who tells his own story, is frankly and undisguisedly human He knows, for instance, that the light in the surf on the rocks is due to phosphorescence, an astonishing piece of knowledge for a fox But the story is so well told, is so interesting, and even exciting, that one does not stumble over unrealities of this kind They seem merely to add piquancy In essentials the story is true to life, and it is admirably told

(4) "The Romance of Animal Arts and Crafts" describes the various styles of architecture adopted by different classes of animal from the beaver down to the caddis-worm Rat-kangaroos, badgers, trap-

door spiders, pocket-gophers, robber-crabs, squirrels, ants, tree-frogs, weaver birds, scarab beetles, and many others come in turn upon the stage From the nature of the case, a book that covers so wide a range must be in the main a compilation But the authors add a good many observations of their own Moreover—a very great merit this—they investigate the current animal stories before accepting them as true There is none of the *credo quia mirabile* spirit They tell us, for instance, that the mole's "fortress" is not the highly elaborated structure which a succession of books on natural history have each in turn still further beautified and complicated, but something much more varying and irregular Altogether it is a very interesting book The illustrations, not very numerous, are good

(5) "Our School Out of Doors" is a book of a very different type It contains a great deal of correct information on interesting subjects, but it is too miscellaneous, and it suffers from the plan on which it is arranged Intended for the use of school teachers, it has one or more chapters for each month This shifting from one subject to another, each very briefly and imperfectly explained, cannot be good for pupil or teacher In May, Composite flowers are, apparently, to be studied before the pupil has any knowledge of the structure of a common buttercup In August, five pages are devoted to "watery wonders" It would be far better to study some of the subjects more thoroughly and to neglect others altogether

OUR BOOK SHELF

Hints to Travellers, Scientific and General Edited for the Council of the Royal Geographical Society by E A Reeves Ninth edition, revised and enlarged Two vols Vol i, pp xi+470, vol ii, pp v+286 (London Royal Geographical Society, 1906) Price 15s net

IN editing this ninth edition of the well-known "Hints," Mr Reeves has taken a point of view somewhat different from that of his predecessor, Mr John Coles, in the earlier editions He says —"As the days of the pioneer explorer of the old type are fast drawing to a close more exact surveys are required than were formerly considered sufficiently accurate for the traveller in unexplored regions" Hence, in the first and larger volume, which is as before, wholly devoted to surveying and mapping, some of the approximate methods, and the tables connected with them, have been omitted, and a higher standard of accuracy is aimed at throughout While it seems possible that the effect may be to discourage some travellers who could still do quite useful surveying work from attempting anything at all, and in others to transform a journey in an unexplored region into a surveying expedition pure and simple, it remains unquestionable that Mr Reeves has produced a condensed treatise on surveying of a high order of excellence

In the section on instruments, the chief new features are the descriptions of the applications of Mr Reeves's devices, the "tangent-micrometer" and "endless tangent screw," to the theodolite and sextant It may be noted that the illustrations of the transit theodolite on pp 29 and 40 are distinctly inferior to those in the older editions, and are scarcely sufficiently clear for their purpose Part iv of this volume, on geographical surveying and mapping has been practically re-written, the main heads dealt with are —(*a*) the determination of fixed points, which includes triangulation with the transit theodolite, latitude and azimuth traverses with normals of angles from stations on the route, and latitudes and longitudes, (*b*) the filling in of detail and route surveying, and (*c*) the determination of heights The first of these sections contains much new and useful matter relating to interpolation reduction to centre and geodetic computations The fifth division, on astronomical observations, has also been to a great extent re-written, the methods of determining longitude by means of lunars, moon-culminating stars, and the eclipses of Jupiter's satellites are omitted, and the space devoted to more complete descriptions of the observations for latitude, time and azimuth great additional clearness being gained in the computations by the free use of diagrams and formulæ The only absolute method of determining longitude described is that of occultations

In the second volume the chief new feature is an extremely valuable section on archæology, by Mr D G Hogarth which gives general hints on methods of recording, cleaning, temporarily conserving, and conveying monuments and objects of antiquity

Sechs Vorträge über das thermodynamische Potential, &c By J J van Laar Pp viii+119 (Brunswick Vieweg und Sohn, 1906) Price 3.50 marks

THIS pamphlet of close upon 120 pages really contains eight lectures, the first and second being as stated in the expanded title, on non-dilute solutions and osmotic pressure respectively These two introductory lectures are polemical, and attack in a lively manner the position assumed explicitly by some implicitly by many, that the so-called osmotic pressure is a real pressure due to the molecules of the solute The author pokes fun at the "dilute school" for pinning their faith to the first term of a diverging series, and for leaving out of account in all their theorising that most essential thing in osmosis the semi-permeable membrane He shows that instead of the "osmotic pressure' depending on the solute it depends fundamentally on the solvent, being mathematically expressible to a first approximation in terms of the difference of the molecular potentials of the two solutions separated by the membrane He makes an appeal in favour of the use of the thermodynamic potential, which is applicable to all cases, including those of weak solutions for which alone the method of the osmotic pressure is of any real service According to his facetious comparison, to explain the accompanying phenomena by an appeal to osmotic pressure is as if one explained an angry man's hasty speech as due to his red face The anger is the cause of both, and in like manner the thermodynamic potential forms the basis of the true theory Then follow the six lectures on the thermodynamic potential and its applications to the problems of chemical equilibrium

Lecture i begins with entropy, deduces the usual thermodynamic relations, and finishes with the general conditions for equilibrium The next lecture contains some simple illustrations leading to the recognition of particular cases of Gibbs's phase rule This important rule is proved in lecture iii, and more complex cases are considered of mixtures of solids liquids, and vapours The fourth lecture discusses the thermodynamic properties of mixtures of ideal gases deduces Gibbs's dissociation formula, and applies it to certain simple cases The effects of

temperature and pressure changes are also considered and the usual formulæ deduced Then follows, in lecture v, the investigation to a first approximation of mixtures of two fluids, leading to the discussion of fusion and solubility curves Finally, in lecture vi, vaporisation curves and the theory of the galvanic cell fall to be considered The same fundamental method is used throughout, the thermodynamic potential being first formulated, and then by differentiation the quantity known as the molecular potential Detailed examples elucidate the method, and there is no doubt that (to paraphrase his own words) the author has demonstrated, not only the great use of the thermodynamic potential, but also the ease with which it can be manipulated Dr van Laar has placed in the hands of the student of thermodynamics a well-written and serviceable pamphlet

The Family By Helen Bosanquet Pp vii+344 (London Macmillan and Co, Ltd, 1906) Price 8s 6d net

THE "Family" is a subject of far greater extent than most persons may think Its importance to society is enormous, though, like the air we breathe, it attracts little attention The variety in the constitution of family life in different places and at different times is extraordinary Its peculiarity in any given case is the result of many influences including long-standing tradition, economic causes, natural instincts, and legislation on succession of property The author has given a valuable *résumé* of facts and opinions derived from more than thirty writers of note, and she has blended them into a pleasant and readable volume which will open out new and wide vistas of interest to most of those who study it She says that the history of the Family "is a great work waiting for a great scholar" It is no disparagement to this book to add that she speaks truly, only it seems to the writer of this notice that a still more important requisite than scholarship is a more enlightened statistical treatment of the subject than it has for the most part yet received

One of the many of these desiderata is an exact analysis of the effects of different forms of the Family on the eventual well-being of the race These have a strong influence on the marriages or on the celibacy of its members The influence of the Family inclusive of religion, in France, is such that in the year 1900 as stated, no less than sixty-four thousand women were immured for life within convent walls Some forms of family life may be found to exert a considerable eugenic effect on the nation, others the contrary, how far has yet to be investigated In the view of the author the power of the Family is not decaying in England She thinks it has developed in a changed direction, through replacing a slavish submission to the head of the family by feelings of willing loyalty The proved habit of the artisan class to contribute to the well-being of the Family is to her an evidence of the strength of the bonds that still unite its members In conclusion, it should be said that this volume contains occasional passages of rare eloquence, such as those in p 160 and onwards, on the very real and spiritual entity of the Family F G

The Evolution of Man a Popular Scientific Study By Ernst Haeckel Translated from the fifth (enlarged) edition by Joseph McCabe Two vols in one Pp xiv+364 (London Watts and Co, 1906) Price 2s net

A TRANSLATION of the fifth edition of Haeckel's famous book is now procurable for two shillings! It is true that the text has been somewhat condensed, and that the beautiful plates of the complete edition have had to be omitted, but the gist of the matter is here, and is illustrated by more than four hundred figures Moreover, a library edition of the complete work is also available to English readers As is well known, the first half of the book contains a general account of the development of vertebrates, and of man in particular, while the second half discusses the chief phyletic stages from protists to man, and the gradually increasing differentiation of the various organs and systems There is a great deal of embryology and comparative anatomy in the book, but there is very little ætiology, and the English title "The Evolution of Man" is rather misleading The original title was "Anthropogenie" Many parts of the book, *e g* those dealing with the development of the fœtal membranes and of the excretory system, are very technical and difficult, serious students of biology will find these intricate subjects more clearly discussed elsewhere, and we do not think that other readers will understand them The translation bristles with mistakes, some of which show that even the translator has not always understood his text The kind of mistake we allude to is translating "Rest der Chorda" as "rest of the chorda," and "Zungenbogen" as "hyaloid bone"

Untravelled England By James John Hissey Pp xviii+459 (London Macmillan and Co, Ltd, 1906) Price 16s

THE author describes how he set forth in search of unfrequented spots in his own country and goes on to provide a pleasing and quietly entertaining account of the out-of-the-way places he visited The start from Eastbourne in a motor car does not, it must be confessed, encourage the reader to expect much in the way of romance, but the motor car, because of its persistently satisfactory conduct does not obtrude itself into the narrative There is no attempt at "fine" writing, yet the author succeeds in maintaining the reader's interest in the English and Welsh villages passed through and in conveying a pleasing impression of the characters of the natives encountered The volume is illustrated by twenty-four half-tone reproductions from photographs taken by Mr Hissey on the journey

A Japanese Singing Kettle

THE town of Morioka is well known for the manufacture of the iron kettle which is indispensable in every Japanese household There exist numerous forms of kettle several dozen shapes may be counted in a single shop but the most frequently occurring forms are cylindrical, pear shaped, and spherical The kettle is used for boiling water by means of charcoal fire for making tea On approaching boiling point some of these kettles begin to sing with quavering sound, which is a combination of different notes peculiar to the form and size of the kettle

There are several arrangements for producing sound, of which the following will indicate the manner in which the vibrations are produced Inside the kettle the bottom is nearly flat On this four pieces of sheet iron, 15 mm sq and 0 4 mm thick, are glued by means of Japan lac (*urushi*), which can well withstand the temperature of boiling water Between the bottom and the plates is an air space nearly ½ mm thick The plates are nearly in a plane and almost touch each other, leaving thin slits between them When the kettle is full the cell is under the water, and some air remains in the cell between the

plates, but as it is the part strongly heated by the fire the cell is filled with steam, which escapes in bubbles through the slits; the water then creeps into the cell, to be converted immediately into steam This process goes on at first intermittently, but it soon reaches a stationary state The bubbling of steam through the slits acts as exciter, and the kettle emits sonorous notes, which may be likened to the ruffling of pine trees by a gentle breeze or the sound produced by stridulating insects The difference of sound is mainly due to the form of the kettle rather than to the method of exciting the vibration To make the kettle sing loudly it is necessary to regulate the fire in such a way that the expulsion of steam bubbles from the cell is in good accord with the natural period of vibration of the kettle, so that it is set in sympathetic vibration Excessive heating is, therefore, unfavourable to singing

Various forms of steam exciter can be easily designed, and different manufacturers seem to have their own speciality When and where this method of exciting the vibration came into use is not well known, but as the kettles were common for many centuries, the exciter seems to have been invented by the amateurs of teaism (*chanoyu*) long before Western science was introduced to Japan

Science College, Tokyo September 27

Bursaries at the Royal College of Science, London

SCIENCE scholars selected from the whole of Great Britain for their ability and promise, maintaining themselves on 17s 9d per week are year by year saved from much privation by secret gifts of small bursaries—see the subjoined audited account for last year

I have no right to ask for help from the generous men who helped me last year but I have all the sturdiness of a chartered beggar I ask in a good cause

It was originally intended that these bursaries should be given only to such National Scholars as required assistance, but some of the subscribers have given me power to assist other students of the college Also one of the two City companies has given me power to grant an occasional bursary of more than 10l It is understood that every student is morally bound to repay this money to the fund at some future time

LAKE BALATON [1]

LAKE BALATON, the largest lake in the Hungarian Plain, occupies a basin of internal drainage at the level of 343 feet above the sea, and has an area of some 230 square miles It is well known from the watering-places and mineral springs upon its shores In 1891 the Hungarian Geographical Society appointed a commission to undertake a detailed investigation of the lake The scheme was supported financially by the Hungarian Minister of Agriculture, the Hungarian Academy of Sciences, and Dr Andor von Semsey The results are being published in three volumes, the first deals with the geography, geology, hydrography, climate, and the physical and chemical characters of the lake water The second volume is devoted to biology, the third to the anthropography, ethnography, archæology bibliography, and the description of the watering-places There is also an atlas Several sections of the work and the topographic atlas have been issued They contain contributions to all three volumes, and illustrate the thorough nature and wide range of the work

The report on the ethnography by the late Dr Johann Jankó, translated by Dr Willibald Semayer is the longest contribution and is perhaps of most general interest It begins with a concise geographical description of all the localities around the shores of the lake, and then gives an interesting discussion of the place-names They are mainly Magyar, with some Sclav and German additions The place-names are classified into groups, based on orographic and hydrographic conditions on plants on the general features of the vegetation on animals on soils and rocks, on echoes (as in Ekko and Zongo odal, "the resounding side"), on industries, ecclesiastical terms, family and personal names, and races (English occurs in the term Angol Zollok, the "English vineyard" and in other names associated with gardens) Other places are named after the days of the week military terms numerals and unnatural death (such as 'Olo" for murder) Historical place-names are placed as a special group and they can be traced back to between the eleventh and fifteenth centuries, they are regarded by Dr Jankó as of especial historical value as showing the unbroken continuity of the Magyar occupation of the Balaton district during the past nine centuries in spite of the invasions of Tartars and Turks The old families who have been domiciled round Lake Balaton for at least a century are mostly Hungarians, 6 5 per cent are Jews, and 1 per cent are foreigners The census of 1890, enumerating a population of 55 000 gave their numerical proportions as follows -98 809

Spezialkarte der Balatonsees und seinen Umgebung By Dr Ludwig von Loczy 4 sheets. Scale 1 to 75,000. (1903)

per cent. Magyar 0·828 per cent. German 0·081 per cent. Croat 0·059 per cent. Slovak and 0·005 per cent. Wend.

The description of the daily life and industries of the inhabitants of the district of Balaton is of especial interest. Some of the people live in artificial caves dug out on the hill-sides in what from the photographs look like deposits of loess. Some of these cave dwellings are high up in the face of the cliff, and they are explained by Dr. Jankó as having been occupied when slopes led up to them and before denudation had cut back the ground and left the ends of the old excavations like hanging tunnels on the face of the cliff. The author figures the picturesque mud-walled thatched houses and the carved wooden furniture, and describes the industries, of which the most interesting is his account of the fishery. He describes the regulations of the Fishers' Guild and the methods of fishing from the fire-hollowed flat-sterned canoes (bottich schiffe), from sledges used on the ice in winter, and by the fish traps composed of labyrinthine fences.

Fig. 1.—Ancient Artificial Cave Dwellings in the District of Lake Balaton.

The archæology of Lake Balaton is described by Gyula Rhé. There are tools and flakes of the Stone age, numerous implements and pottery of the Bronze age, and well-preserved remains of a Roman settlement at Pogany-telek.

The three sections of the first volume deal with seasonal plant distribution and with the physical characters of the lake water. The work on phenology was begun by Dr. Moriz Staub and continued by Dr. Bernatsky; extensive observations on the time of blooming of *Galanthus nivalis*, *Corylus avellana* and *Cornus mas* have been used to map out the part of Hungary between the Danube and the Drave into seven zones characterised by the earliness or lateness of the vegetation.

The investigation of the physical characters of the lake water has been conducted by Dr. von Cholnoky and Baron Harkanyi. The former has determined the transparency of the water under different conditions of wind and season, and its essential colour, which varies from the highest to the middle numbers (11–6) in Forel's scale. He also discusses the influence of movements of the water on its colour, and the complex colour and light effects produced by wind and ripples. The sky has an especially powerful effect on the colour, as the lake is in open plains with low banks, but different colours are seen under the same sky conditions, and they are explained as polarisation effects. The apparent uplift of hills by mirage is illustrated by a telephotograph and by a series of views showing the different elevation of distant hills under varying conditions of refraction. The discussion of the colour effects is illustrated by excellent sketches showing colour effects on the shores of the lake under different climatic conditions, and is followed by an investigation by Baron Harkanyi on reflection effects from moving water.

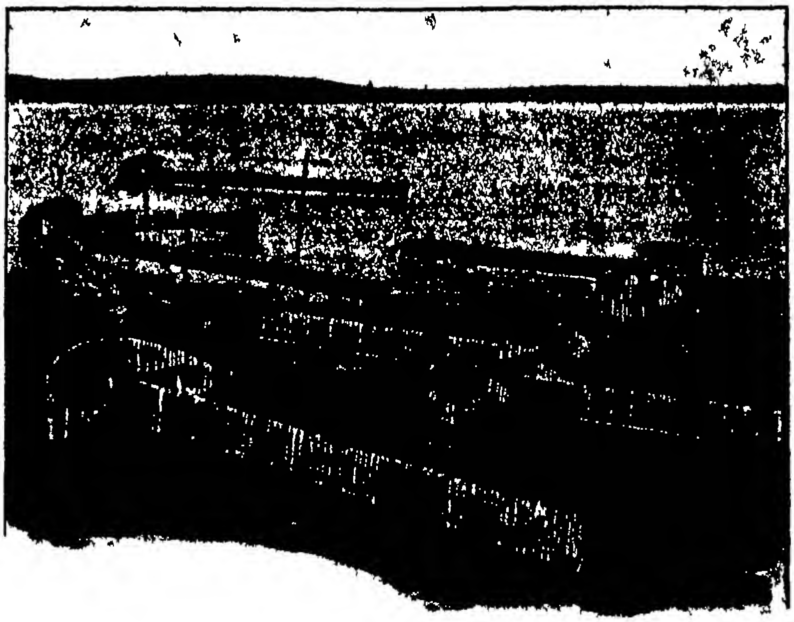

Fig. 2.—Fish Traps on Lake Balaton.

The reports on the biological sections of the work are represented by two sections. A monograph of the diatoms by Dr. Josef Pantocsek gives a systematic account of the 288 species, many of which are new. The Mollusca are catalogued by Dr. Weiss and Theodor Kormos. Dr. Weiss's list raises the number

of known species in the fauna to 106. Contributions to the knowledge of the plankton are given by Dr. Geza Entz; he describes twenty-three species of Peridiniaceæ, and figures the seasonal variations of *Ceratium hirundinella*, which lives in the lake throughout the year, and is common from May to November.

The last part of the whole work, the bibliography, has been compiled by Dr. Julius von Sziklay. It enumerates all the independent works, with summaries of their contents, and has special sections for maps and for contributions in journals and serials.

The Hungarian Geographical Society is to be congratulated on this valuable contribution to natural science. The monograph on Lake Balaton will be of value to all students of the natural history and geography of Central Europe, and its summary of modern methods of research will be of use to students of lakes elsewhere. Moreover, the description of the country, revealing the quiet charm of its scenery and the many interests in the life of its people, should lead more visitors to this attractive district.

A 100-INCH REFLECTING TELESCOPE.

As time passes and astronomical work advances there is a greater demand, year by year, for more powerful instruments of research. Fortunately, instrument makers have so far been able to fulfil the requirements for large refractors and reflectors, but a few years ago the time seemed to be reached when further progress appeared a long distance off. At the present day there are refractors in existence the object-glasses of which are as large as 30, 36, and 40 inches in diameter, while the greatest glass mirror that has been used measures 60 inches in diameter.

In the case of the largest refractor, namely, that erected in the Yerkes Observatory in America, it seems possible that the size of this form of telescope has nearly reached its limit. The reasons for this are that, not only is it extremely difficult and costly to cast and figure lenses of such dimensions, which to give the best definition must be practically flawless, but the mounting has to be so immense and strong, and consequently very expensive in proportion.

It must be remembered that in the refracting form of telescope the object-glass has to be placed at the *upper* end of a long tube, while the observer takes his place at the lower end; these ends have to be very rigidly connected together, and the whole tube mounted so as to be capable of being moved in any direction. Thus in the case of the Yerkes telescope the tube had to be 62 feet long (weighing six tons), and the whole mass of metal that required moving every time the telescope was required in a different position was twenty tons. This will give some notion of the engineering difficulties that are involved in large refractors. In reflectors, on the other hand, the mirror is placed at the *lower* end of a comparatively light tube, and as close as possible to the mounting on which it is carried. In fact, in the case of the late Dr. Common's 5-feet reflector a means was adopted of actually floating the mirror.

In considering, therefore, the construction of telescopes much larger than those that already exist attention is naturally being paid more to the reflecting type than to refractors. Further, it is not necessary that the glass casting for a mirror should be so perfect as that required for an object-glass, for in the former case only a perfect reflecting *surface* is required, while in the latter the light has to pass through the whole mass of glass. It is obvious, then, that much larger discs of glass can be made which may be suitable for reflectors but useless for refractors. Aperture for aperture, a mirror costs about one-tenth the price of an object-glass, and this gives some idea of the extra work and risk involved in producing a good object-glass.

The expense attached to the mounting of a reflector is also considerably less than that of refractors when large instruments are in question.

Now not only is the reflector the less expensive of the two forms of instruments, but it has many distinct advantages optically. Thus chromatic aberration is a thing unknown in reflectors. Again, light being totally reflected from the silvered surface of a mirror is not lost like it is in refractors, where it always has to pass through the object-glass, and is consequently partially absorbed.

Mirrors are, however, easily tarnished and affected by changes of temperature, but these disadvantages do not counterbalance the many points in their favour, to which reference has been made, when exceedingly large instruments are under consideration.

In the Proceedings of the American Philosophical Society (vol. xlv., No. 182, p. 44, 1906) Prof. E. C. Pickering communicated a paper entitled "An International Southern Telescope," and in it he strongly advocated the erection of a large telescope of the reflector type. His proposal was that the telescope should have a diameter of about 84 inches and should be set up in some locality such as South America or South Africa, where the observing conditions are considered very favourable. Towards the end of the paper Prof. Pickering referred to the important work that could be accomplished by means of such a large reflector, and mentioned that the name of a donor "could in no way be better immortalised than by associating it with such a real advance in the greatest problem to the solution of which the mind of man has aspired—the study of the sidereal universe."

We learn now from the current number of the *Astrophysical Journal* (vol. xxiv., No. 3, October) that Mr. John D. Hooker, of Los Angeles, who on former occasions has rendered financial assistance to astronomy, has presented to the Carnegie Institution of Washington the sum of forty-five thousand dollars to purchase a glass disc 100 inches in diameter, 13 inches thick, and 50 feet focal length, and to meet other expenses incident to its construction. These latter will include the erection of a building in which the mirror can be ground, figured, and tested, the construction of a large grinding machine, with crane for lifting the mirror ($4\frac{1}{2}$ tons); the provision of a 54-inch glass disc to be made into a plane mirror for testing purposes, and other necessary items.

The large mirror is intended for use at the Solar Observatory of the Carnegie Institution situated on Mount Wilson, in California, and under the directorship of Prof. G. E. Hale. This observatory has already a 60-inch mirror in its optical shop, and at the present moment it is being tested. In the case of the new 100-inch reflector, we are told the St. Gobain Company expresses its deliberate opinion that such a disc, 13 inches thick, can be produced and that the Company will be able to carry out the order which has been given to it.

The grinding and figuring will be entrusted to Prof. G. W. Ritchey, and no unsurmountable difficulty is anticipated by him in bringing such a mirror to a high order of perfection. The 60-inch mirror now nearly completed, is the largest he has yet attempted, and this is now nearly ready for mounting.

At present no financial provision has been made for the mounting and housing of this 100-inch reflector, but as the mirror will take, as we are told, about four years to complete there is no immediate hurry.

The experience gained by the form of mounting adopted for the 60-inch mirror will be valuable when the time comes for the erection of the 100-inch mirror, and funds will no doubt soon be found when the right moment arrives

Already the United States is the possessor of the two largest refractors and silver-on-glass reflectors This new monster will afford her another means of greatly extending astronomical knowledge, which has made such vast strides during the last decade owing to these increased aids to observation

AN EXPERIMENT IN INSECT-EXTERMINATION [1]

IN the year 1900 the sugar-cane planters of Hawaii were seriously alarmed by the appearance in considerable numbers in their plantations of an introduced hemipterous insect allied to the cicadas and commonly known as the cane leaf-hopper, but designated scientifically *Perkinsiella saccharicida* Since that date the pest has increased to an enormous extent, with an estimated loss of many millions of dollars to the planters Fortunately, the leaf-hopper has a certain number of enemies among the insects indigenous to Hawaii, since had it not been for the extent to which it was held in check by their attacks it seems probable that sugar-growing would by this time have become absolutely impossible in the islands

These indigenous enemies were, however, utterly unable to cope in a thoroughly efficient manner with the swarms of the leaf hopper, and it became apparent that unless some other means of diminishing its numbers were discovered the sugar industry of the Sandwich Islands would be practically ruined Accordingly, the officials of the Entomological Division of the Planters' Association at Honolulu set to work with commendable energy and enthusiasm to endeavour to find an efficient and satisfactory remedy It appears to have been soon decided that such a remedy would most likely be discovered in the form of insects which would prey upon the leaf-hoppers with greater vigour than any Hawaiian species, and in 1903 and the two following years expeditions were organised to North America Australia, and Fiji with the view of discovering such insects

In due course a number of species inimical to the cane leaf-hopper were brought to light, and the present elaborate bulletin (of which one part has been already briefly noticed in our columns) is devoted to the description and life-history of leaf-hoppers and their enemies, together with an account of the experiments which have been made in introducing and acclimatising certain of the latter into Hawaii

The list of insects parasitic on leaf-hoppers is a very long one and comprises representatives of several orders, although the great majority belong to the Hymenoptera For our present purpose attention may be concentrated on the few species it has been found advisable to introduce into Hawaii In the case of the introduction of such parasites four points are essential —(1) Their effectiveness as destroyers of the pests, (2) the possibility of successful transportation, (3) the probability of their thriving in the new country, and (4) their rapidity of increase when introduced The choice was soon narrowed down to certain minute Hymenoptera which feed upon the eggs of leaf hoppers, namely, to species of Anagrus and Paranagrus in the family Myrmaridæ and to one of Ootetrastichus among the Eulophidæ The members of the two first genera complete their life-cycles in about three weeks, breed at about the same rate throughout the year, and are largely parthenogenetic Ootetrastichus, on the other hand, takes fully twice as long to complete its cycle, but produces twice as many eggs, and is wholly parthenogenetic. *Caeteris paribus*, the products of the myrmarids at the end of six months will, however, be a million times more numerous than those of the other genus On the other hand, the ootetrastid is not only more hardy, but has the advantage that each individual is bred at the expense of the whole contents of the egg-chamber of the leaf-hopper instead of destroying only a single egg

Of the four species introduced one of Paranagrus is at present the most effective, but the Ootetrastichus is slowly but surely increasing in numbers, and is eventually expected to prove the most effective For further details respecting these interesting and to a great extent even at present successful experiments, our readers must be referred to the Bulletin itself

THE FLIGHT PROBLEM

THE real "flights" not "jumps," which Mr Santos Dumont has been making at Paris with his new aeroplane have directed the attention of the whole aeronautical and motor world in the direction of the problem of flight Further, tempting prizes have now been offered which will undoubtedly stir up other workers to take up the problem and so increase the chance of rapidly advancing the progress of aerial navigation

In addition to the Archdeacon prize of 200*l* for a half-mile course and to the enterprising offer of the *Matin* of 4000*l*, which was subsequently increased to 10,000*l* by public subscription for the first traveller who succeeds in covering the distance between Paris and London in 1908, the *Daily Mail* has now come forward with the offer, open to the world, of 10,000*l* to the first person who shall fly by aeroplane from London to Manchester in twenty-four hours, including two stops to take in supplies of petrol

Such large prizes will certainly go a long way towards giving a strong impetus to the manufacture of aeroplanes and also to the motor industries to produce the lightest forms of petrol engines In fact, a great number of people will almost immediately set about experimenting with aeroplanes in order to compete for the prizes We read that already Mr Santos Dumont has given an order for a lighter and more powerful engine, namely, a 100 horse-power motor which will weigh no more than 200 lbs

Since Mr Santos Dumont's successes were announced, several references have been made to the experiments which have been carried out by the brothers Wright in America, but very little is known about their results, since they have purposely avoided publicity, according to the views of Sir Hiram Maxim, as stated in the *Daily Mail*, they have a new motor to their aeroplane which is twice as effective as their previous one, and they hope to "fly with it 200 to 300 miles without stopping"

Up to the present time there has not been any great inducement for workers to come forward and demonstrate publicly the capabilities claimed for their machines The rewards now offered will no doubt serve as an incentive to them, and possibly others, to enter the arena and prove in open competition the efficiency of their designs

NOTES

THE meetings for the discussion of important contributions to meteorological literature, arranged by the director of the Meteorological Office, will be resumed on Monday, November 26, at 5 p.m., with a discussion of Mr. J. Aitken's paper "On Dew."

A REUTER message from Toronto records that on November 19 electrical energy generated at Niagara Falls, eighty miles away, was delivered there for the first time. A supply of 40,000 horse-power is available.

CAPTAIN AMUNDSEN, the leader of the *Gjoa* Polar Expedition, and his companions arrived at Christiania on November 20. Among the large number of people who assembled on the landing stage to receive the explorer were the President of the Storthing, the members of the Government, and the magistracy, the President of the Municipal Council, the admirals of the station, the general in command of the capital, and the president of the Norwegian Geographical Society.

ON November 13, at 11 p.m., a sharp shock of earthquake was felt both in the south and the north of Jamaica. It was immediately followed by a second shock, the heaviest experienced in Kingston for many years. From Perth, Western Australia, it is reported that an earthquake was felt at 3.20 p.m. on November 19 along the whole of the coast from Albany to Sharks Bay. The shock was very severe at Perth, Busselton, Geraldton, and Marble Bar.

THE spermatogenesis of one of the swallow-tailed butterflies (*Papilio rutulus*) forms the subject of a long article by Dr. J. P. Munson in the Proceedings of the Boston (U.S.A.) Society of Natural History (vol. xxxiii., part iii.).

IN the *Irish Naturalist* for November Mr. R. J. Ussher gives an account of the excavation of certain "hyæna-dens" in the Mammoth Cave near Doneraile, county Cork. The discovery of the system of caves of which this forms a part is recorded in the Proceedings of the Royal Irish Academy for November, 1904. Seventy-six baskets of bones and teeth were obtained from the Mammoth Cave and dispatched to the Dublin Museum. All the remains identified appear referable to the ordinary cavern species, but the remains of the cave hyæna are the first record of the occurrence of that species in Ireland.

Two articles are included in vol. lxxxiv., part iv., of the *Zeitschrift für wissenschaftliche Zoologie*, one by Mr. F. Hempelmann on the morphology of two marine annelids of the genus Polygordius, and the second by Dr. E. Zander on the filtering apparatus of the gills of teleostean fishes. In 1903 the latter author discovered a certain appendage to the gill-filters of fresh-water fishes, and the present paper is based on a fuller study of this structure, more especially in marine species, of which a large number has been examined. It has been found that the development, and in some degree also the function, of the filtering apparatus vary considerably according to the mode of life, bottom-dwelling species using it to aid in the supply of nutriment.

AN interesting article on entomological photography appears in *Focus* of November 21. The object of the article is to show how photographs of many kinds of insects may be taken in all stages of their existence from living specimens in captivity, and in some instances amid imitations of their natural surroundings. When aquatic insects form the subject of the experiment, a narrow and deep tank is, of course, essential. When dealing with butterflies, it is found most advantageous to take them just after leaving the chrysalis, or, failing this, they may be made quiescent by the application of a small quantity of chloroform. The photograph of a group of five "tortoise-shells" appears very successful. In the case of night-flying moths, it is impossible to display the full characters of the species from living specimens when at rest, while to depict them flying is likewise an impossibility. To overcome these difficulties the photographer has resorted to the plan of first photographing mounted specimens in the positions desired, and then combining the photograph thus obtained with one of a suitable background. If a suitable landscape-negative has been previously taken, by placing this behind the focusing screen the moths can be arranged in such a position that they will appear exactly in the right place in the compound picture.

IN the course of a paper on the papillary ridges and papillary layer of the skin of the hand and foot of mammals other than man, published in vol. xli., part i., of the *Journal of Anatomy and Physiology*, Dr. Walter Kidd points out that these structures attain their maximum development in the lemurs and their relatives. "These characters suggest very clearly that in this group of animals the sense of touch is extremely important. . . . If one bears in mind that three [groups] of them are nocturnal and arboreal and the other two diurnal and arboreal, one can gather from these facts the great importance to them that their sense of touch should be very acute. A continual need of their arboreal lives is that they should maintain by reflex means their equilibrium, and I would suggest that in their highly developed papillary ridges and papillary layer of the corium they possess most efficient structures for the transmission of impulses to their nerve-centres for the performance of this important function." To the same issue Mr. E. J. Evatt contributes a paper on the development of these structures. The other articles are mainly devoted to the description of various monstrosities and other abnormalities.

IN the Proceedings of the American Academy for October there is an interesting study of inheritance in fishes by Mr. A. P. Larrabee. In the majority of the teleosts the fibres of the two optic nerves do not interlace at the chiasma, but remain distinct, and it has been shown for certain species that specimens in which the nerve running to the right eye is dorsal, and specimens in which the reverse is the case, are almost equally frequent. The present investigation, commenced by Dr. W. E. Castle and completed by Mr. Larrabee under his direction, was undertaken with the view of determining whether this character is heritable, and if so in what manner. Crossings were made with the brook trout and with the cod, and the rather remarkable conclusion is reached that the character is not inherited at all. Of 971 trout, for instance, in both the parents of which the right nerve was dorsal, 52 per cent. had the right nerve dorsal, while of 1519 with unlike parents 56 per cent. had the right nerve dorsal. The character does not appear to be affected by gravity, the dimorphism is not due to an earlier development of one of the optic nerves, and in monstrous two-headed specimens of the trout the two heads differ in structure as often as not. Practically speaking, it seems to be a matter of chance which nerve is dorsal. There is, however, a curiously persistent preponderance of cases with the right nerve dorsal, and Dr. Castle in a footnote directs attention to the apparent similarity of the phenomenon with the more frequent occurrence of polydactylism in guinea-pigs on the left side of the body.

IN the first part of vol. xxxvi. of Gegenbaur's *Morphologisches Jahrbuch* Prof. Schmaltz, of Berlin, furnishes

further information with regard to the assertion (mentioned some months ago in these columns) that a pleural cavity is lacking in the Indian elephant. The author's observations are based on dissections of four elephants, one from the Berlin Zoological Gardens and three from a circus. In each instance the structure of the pleural viscera was of the same type. The heart was normal. The lungs possessed a dense fibrous capsule, but between their outer surface and the wall of the thorax occurred a homogeneous mass of connective tissue, completely filling the cavity of the chest. The connective tissue presented no signs of being a pathological product, and, in the author's opinion, it must consequently be accepted as a fact that a pleural cavity is absent in the Indian elephant. In a second article Mr. A. Rauber records and figures two instances of the occurrence of an "intermetatarsal bone" in the foot of the human subject. The bone in question is an ossicle wedged in between the entocuneiform of the tarsus and the bases of the first and second metatarsals. The number of recorded cases of a similar abnormality is now brought up to eighty-eight, and the author concludes by discussing the bearing of this feature on the theory of a lost digit. The contents of the same issue also include an article, by Dr. C. Gruber, on the structure and development of the reproductive organs of the guinea-pig; a second, by Dr. W. Braun, on the development of the pancreas in the midwife-toad; and a third, by Mr. Max Borchert, on the central nervous system of the torpedo.

THE *Philippine Journal of Science* for September (i., No. 7) contains a long paper on beri-beri by Mr. M. Herzog, who believes that this disease is an infective one, the organism of which has yet to be discovered; notes on Philippine and other birds, by Mr. R. C. McGregor; and a description of a new genus and species of Culicidæ, by Mr. C. S. Banks. This mosquito (*Worcesteria grata*) does not bite, and its larvæ destroy numbers of noxious forms of Culicidæ. The genus is near the genera Megarhinus and Toxorhynchites. The number is well illustrated with many plates, and is a most creditable production.

IN the Bulletin of the Johns Hopkins Hospital for November (xvii., No. 188) Dr. C. W. Eliot discusses the future of the medical profession, and concludes that in the course of time it will have the satisfaction, not only of ameliorating the condition or prolonging the life of the suffering individual, but also of exterminating or closely limiting preventable diseases. Notes on the International Congress of Tuberculosis, Paris, 1905, are contributed by Dr. H. B. Jacobs, and on the advantages of local sanatoria in the treatment of consumption by Dr. D. R. Lyman. Governor John Winthrop, jun., of Connecticut, a physician of the seventeenth century, is the subject of a paper by Dr. W. R. Steiner, and Prof. Welch's address on the unity of the medical sciences, delivered at the dedication of the new buildings of the Harvard Medical School, is published in full.

THE issue of selected papers on rubber from the *Kew Bulletin* as No. 7 of the additional series is opportune at the time when this product is receiving so much attention. Not only do the papers furnish a historical account of the gradual accumulation of knowledge that is bearing fruit at the present day, but old facts served up as new, such as the artificial production of rubber, are here placed in proper perspective. The most recent papers are the synopses of the genera Kickxia and Funtumia, by Dr. O. Stapf, published in the *Kew Bulletin*, 1905, and a note on the rise and fall in prices of Para rubber contributed by Mr. J. H. Hillier to the part lately issued.

A CATALOGUE of botanical slides issued by Mr. A. Peniston, Montpelier Terrace, Leeds, can be recommended to the notice of those desiring microscopical slides of practical educational value, illustrating the chief features in the taxonomy and anatomy of plants. Of the slides examined, the root apices showing mitoses and the transverse section of Equisetum root were especially good, and all were satisfactory. Messrs. Clarke and Page, of London, supply botanical and geological preparations, but make a greater speciality of marine slides, which, judging from specimens seen, will be found suitably and well prepared.

THE annual report for 1905 of the Royal Botanic Gardens, Ceylon, contains eight reports by assistants, in addition to the general report by the director, Dr. J. C. Willis. The branch gardens at Badulla and Anuradhapura were closed in favour of a botanic garden at Mahailuppalama, where an experiment station has already been established. Rubber has, of course, monopolised most attention, but the production of the oils of cocoa-nut, citronella and cinnamon shows a considerable increase, and in the market for coca leaves Ceylon provides the standard. The curator of the Peradeniya gardens records the failure of the attempt to propagate Hevea by cuttings; as a substitute for boxwood edgings in tropical gardens he recommends cuttings of *Malpighia coccifera*.

THERE are several facts and observations, interesting to botanists, on the subject of xerophytes and plant transpiration in the publication No. 50 of the Carnegie Institute of Washington entitled "The Relation of Desert Plants to Soil Moisture and to Evaporation," representing investigations by Dr. B. E. Livingston at Tucson, in Arizona. With regard to the soil, it was found that the deeper layers contained an adequate supply of water even at the end of the dry season, this being due partly to the formation of a dust mulch. Cacti showed no greater osmotic pressure in the cell-sap than plants in humid regions. An ingenious evaporimeter, consisting of a porous clay cylinder attached to a burette and water receiver, was devised for comparing evaporation with transpiration. The author expresses the opinion that air temperature, and not light, is the main controlling factor in the rate of transpiration.

PROF. POTONIÉ, of Berlin, contributed a paper (an abstract of which has now reached us) to Section K at the York meeting of the British Association, in which he pointed out the strict parallelism that exists between the different kinds of peat and the different kinds of coal (which is simply fossil peat). When conditions are such that organic remains collect under terrestrial conditions we have ordinary peat formed. This corresponds exactly with "bright" coal. When, on the other hand, organic remains collect under water, the result is an organic slime which the author calls "sapropel," becoming of a gelatinous consistency ("saprokoll") when subfossilised. This, according to Prof. Potonié, is exactly equivalent to the "dull coal" or "cannel coal" of Carboniferous age. When terrestrial and aquatic conditions have alternated during the accumulation of organic remains, we obtain "strata-peat" or "strata-coal," i.e. interbedded saprokoll and peat, or "bright" and "dull" coal. The chemical and physical properties of these varieties correspond very closely, the cannel coal being gas coal and saprokoll containing much more gas than genuine peat. The author regretted that living peat bogs were so extensively killed

by drainage, and pointed out that we were thus destroying a possible source of fuel supplies when our coal should be exhausted.

THE Channel tunnel project forms the subject of an article in the *Engineer* (vol cii, No 2654) Particulars are given of what has been accomplished, from an engineering and scientific point of view, upon the other side of the Channel towards the solution of the great international problem

AT the Institution of Civil Engineers on November 13 a paper was read on single-phase electric traction by Mr C F Jenkin A paper on electric traction on railways, by Messrs Mordey and Jenkin, was read before the institution in 1902 The object of the present paper was first to bring the previous account of the different systems up to date, and to show how far the conclusions then arrived at have to be modified in the light of recent experience, and then to describe the equipment required for single-phase working and to discuss the different problems which arise in connection with it Little advance has been made in continuous-current working The voltages have risen a little, and in a few cases pressures of 1000 and 3000 volts are in use The principal advances in three-phase working have been the completion of the Zossen experiments, the opening of the Valtellina line, and the adoption of three-phase working for the Simplon Tunnel Experience has confirmed Messrs Mordey and Jenkin's conclusion that the single-phase is the only system which can satisfy all the requirements of a general system

ACCORDING to the official statistics published in the Mines and Quarries General Report (part iii, 1906) the output of coal in Great Britain in 1905 was the highest hitherto recorded, being as much as 236,128 936 tons Of this total, 47,476,707 tons were exported, and 19,255,555 tons were used in the manufacture of pig iron The home consumption was 3 91 tons per head of population Statistics relating to the manufacture of coke and briquettes were collected for the first time, the production of coke in 1905 having been 18,037,985 tons, and that of briquettes 1,219,586 tons There were 31,060 coke ovens in operation Of these, 25,514 were of the beehive type, and there were 2233 Coppée ovens, 726 Simon-Carvés ovens, 503 Otto-Hilgenstock ovens, 470 Semet-Solvay ovens, 72 Koppers ovens, 52 Bauer ovens, and 1490 other kinds The production of iron ore was 14,590,703 tons, which yielded nearly one-half of the total quantity of pig-iron (9 608,086 tons) made in the country Copper, lead, silver, and tin show an increase on the figures of 1904, both in the amount and in the value of the metal obtained

A SIMPLIFIED method of transforming readings of the Fahrenheit thermometer into centigrade values and *vice versâ* is given by Dr Hellmann in No 38 of the *Naturwissenschaftliche Rundschau* The ordinary formulæ, for example $C=5/9(F-32)$, are not adapted for rapid calculation. The modified formulæ

$$C=(\tfrac{1}{2}-\tfrac{1}{2}\cdot\tfrac{1}{10}-\tfrac{1}{2}\cdot\tfrac{1}{100})(F-32), \text{ and } F=(2-\tfrac{2}{10})C+32,$$

on the other hand, containing decimal fractions, lend themselves much more readily to the purpose To transform, for example, 110° F, we have 110−32=78, and the centigrade value becomes 39+3 9+0 4=43° 3

A REVISION of the atomic weight of bromine made by Mr Gregory P Baxter in the chemical laboratory of Harvard College is published in the Proceedings of the American Academy of Arts and Sciences (vol xlii, No 11) Considerable uncertainty exists as to the purity of the materials employed in several of the earlier determinations, owing principally to the fact that while it is easy to eliminate metallic impurities from silver, it is not so easy to ensure the absence of occluded gas Two different methods were adopted in the determinations in one, highly purified silver was converted into silver bromide, in the other, the ratio of silver bromide to silver chloride was determined by acting on the former with purified chlorine As many different methods of purification as possible were employed for the materials used Eighteen determinations by the first method gave a value of the atomic weight varying from 79 950 to 79 955, silver being taken as 107 930, thirteen determinations by the second method ranged from 79 951 to 79 955 The average of both series was 79 953

A VOLUME of essays, or rather lectures, by the late Lieut -General A. Lane-Fox Pitt-Rivers, edited by Mr J L Myres, will be issued immediately by the Oxford University Press Mr Henry Balfour, the curator of the Pitt-Rivers Museum, has written an introduction to the volume, which is entitled "The Evolution of Culture"

THE eleventh volume of the complete works of Christiaan Huygens, which are being published from time to time by the Société Hollandaise des Sciences, is in course of preparation and will, it is expected, be ready in about a year The tenth volume of the works was reviewed in our issue for August 17 1905 (vol lxxii, p 362) Meanwhile, an extract from the eleventh volume has been issued separately under the title "Travaux divers de Jeunesse, 1645–1646" it is edited by M D J Korteweg and published by M Nijhoff, of the Hague Several papers written by Huygens in 1645 and 1646—that is to say in his seventeenth and eighteenth years—are included in this preliminary publication

MESSRS WILLIAMS AND NORGATE have sent us a prospectus of "The Paintings of Antiquity" edited by Herr Paul Herrmann, and published by Herr F Bruckmann, of Munich The work is to be published in sixty parts and will contain about 600 plates, of which twelve to fifteen will be coloured Six parts will be published annually The nucleus of the collection of pictures is formed by reproductions of wall paintings removed from their original positions in houses at Pompeii, Herculaneum and Stabiæ, and taken to the Museo Nazionale at Naples A limited selection of mosaics will be included Whatever paintings have been preserved of the ancient Greek and pre Hellenic periods will be comprised in the collection and the work will also include the most important of the mummy portraits from the Fayûm

OUR ASTRONOMICAL COLUMN

ANOTHER NEW COMET (1906*h*) —A telegram from the Kiel Centralstelle announces the discovery of a comet on November 14 by Mr Joel Metcalf of Taunton (Mass) Its position on that date at 10h 04m (Taunton M T) was R A =4h 6m, dec =2° 16′ S, and the apparent direction of its motion is given as south-west This position is about half-way between 35 and ξ Eridani, and crosses our meridian shortly after midnight The comet's magnitude is given as 12 0

A second telegram states that this object was observed by Mr Hammond at Washington on November 16, its position at 11h 38m (Washington M T) being

R A =4h 4m 11 4s, dec =2° 46′ 55″ S,

and its magnitude 11 0

COMET 1906*g* —From observations made on November 10, 11, and 12, Herr M Ebell has calculated a set of elements and an ephemeris for comet 1906*g* the discovery of which was announced in these columns last week The elements show that this comet passed through perihelion on November 7

Ephemeris 12h Berlin

1906	α (true) h m s	δ (true) ° ′	1906	α (true) h m s	δ (true) ° ′
Nov 20	10 0 55	24 28.1	Nov 28	10 41 34	34 10.6
24	10 20 51	29 24.7	Dec 2	11 2 57	38 38.5

The brightness of this object is now decreasing, and will be 1.04 times that at the time of discovery on November 24, when its magnitude was 8.5 (Kiel Circular No. 92). In announcing the discovery of this comet last week it was stated that the magnitude was not given in the Kiel telegrams. Prof. Kreutz writes to point out that the magnitude was given, and we regret that the group of figures containing it was mistranscribed whilst decodifying the message.

HALLEY'S COMET.—In vol. cxv., part v., of the *Sitzungsberichte der kaiserlichen Akademie der Wissenschaften*, Dr. J. Holetschek discusses the probable time at which Halley's comet may be looked for with reasonable chance of success during its forthcoming return. By reason of a particular combination of perturbations the present period of revolution ($74\frac{1}{2}$ years) is the shortest observed since 1531, but after determining the comet's distance from the earth and the sun during the oppositions of 1906–9, Dr. Holetschek concludes that there is no great likelihood of this object being re-discovered before the latter part of 1908. At the end of 1909 it should certainly be easily observable, and during the second half of March 1910 it should become a naked-eye object. According to the elements published in the *Connaissance des Temps* (1900) the comet is due to pass through perihelion on May 16, 1910.

A BRIGHT METEOR.—An exceptionally beautiful meteor was observed by Mr. Rolston at the Solar Physics Observatory, South Kensington, at 13h. 26.5m. on November 17. The approximate positions of the beginning and end of the trail were $\alpha = 75\frac{1}{2}°$, $\delta = +24°$ and $\alpha = 88°$, $\delta = +14°$ respectively. The narrow fan-shaped head was nearly as bright as Jupiter, and left behind it a shimmering trail of a reddish colour, similar in appearance to the shower of sparks which come from a suddenly-braked train wheel. The duration of the meteor's flight was little more than one second, and the trail died away immediately.

THE UNITED STATES NAVAL OBSERVATORY PUBLICATIONS.—We have received from the U.S. Naval Department a copy of part iv., vol. iv. (second series), of their Publications, containing, in addition to a profusely illustrated account of the 1900 and 1901 eclipse expeditions, previously described by Dr. W. J. S. Lockyer (NATURE, vol. lxxiii., p. 486, March 22, 1906), a number of tables for use in the reduction of astronomical observations. The reduction tables for transit-circle observations contained in part ii. are only suitable for the Naval Observatory, with the exception of the refraction tables, which are based on the Pulkowa values.

Part iii. contains reduction tables for equatorial observations, including those for differential refraction and instrumental corrections. In part iv. there is a very interesting discussion of the present status of the use of standard time, in which a fairly complete account of the standard times in use in every part of the earth is given.

The conversion tables and the summaries of the time in each country giving the standard meridians and the relation to the standard times of other countries should prove very useful for reference purposes.

THE ACTION OF TRAM-CAR BRAKES.

THAT steep gradients can be overcome by mechanically propelled tram-cars—as compared to ordinary railway trains—and that street-cars are driven on public thoroughfares more or less crowded with other traffic, renders the brake question one of considerable importance. The lamentable accident that occurred at Highgate last June affords strong evidence of this. On June 23 a double-deck bogie car became unmanageable and ran at a great pace for a distance of about three furlongs down the hill extending southwards from Highgate Archway to the Archway Tavern. The gradients here though considerable are not excessive for tramway work when the cars are operated with due care. The lines have an inclination of about 1 in $22\frac{1}{2}$ on the hill, but in other parts of the line the gradient is 1 in 18, whilst gradients of 1 in 9 have been authorised. Colonel Yorke, to whose full and admirable report on the accident we shall make frequent reference, has said that the Board of Trade insists on track brakes being fitted to all cars running over gradients of 1 in 15, the speed being limited to six miles an hour. Of the passengers on the car, only a few were slightly injured, but three persons in the street were killed and twenty were injured, some seriously. The runaway car collided with a hearse, a furniture van, a motor-omnibus, and another van, being finally brought to rest by a stationary car at the terminus. The chief lesson to be gained from the disaster is connected with the action of brakes on vehicles of this description.

The car would carry thirty passengers inside and thirty-eight on the top. It was of the double-bogie type with eight chilled cast-iron wheels and maximum-traction trucks, the small wheels leading. There was a 35-h.p. motor on each bogie truck, the motors being geared to the axles of the large driving wheels. The general design appears, from the descriptions given in Colonel Yorke's report, to be of a well-known type in which the effort is made to get the maximum weight for adhesion on the driving wheels without the use of a motor on each axle, the latter being an arrangement which, with a double-bogie car, would need four motors. With this design the distribution of weight becomes a matter of great importance. The car in question weighed twelve tons unladen, and the engineer to the owners, the Metropolitan Electric Tramway Company, has estimated that four tons were carried upon each of the driving axles, and two tons upon each of the pony axles.

The car had hand brakes, of the usual description, working brake blocks on all eight wheels, and was also fitted with electromagnetic track brakes having two shoes on each bogie. There were also four sand-boxes operated from the driving platform.

The track brake has been introduced at a comparatively recent date, and is especially for tramway work. Its failure to stop the car in the instance under consideration is therefore a circumstance worthy of close inquiry. There are two leading descriptions of electromagnetic track brake or slipper brake, but Colonel Yorke's report does not specify the type fitted, although the description fairly well indicates which was used. There are certain features common to both types, and each acts by the brake shoes being strongly attracted to and pressed on the rails by magnetic force. The magnets formed by the brake shoes are energised by current generated by the car motors. Colonel Yorke gives a concise description of the brakes on the car under notice. Each brake shoe consisted of two narrow steel plates 15 inches long, placed side by side, with a small interval between them, thus forming the poles of a powerful electromagnet excited by current supplied by the motors acting as generators. The shoes of the brakes in question were also connected to the brake blocks which formed part of the hand brakes, so that the latter pressed against the wheels, and therefore automatically came into play when the track brakes were applied. This is a usual arrangement. With electromagnetic brakes of this description there is a retarding action due to the motors running as generators, and therefore putting a braking action directly on the axles. It will be understood that the hand brakes can be operated without putting the magnetic brake in action. Resistances are provided between the motors and the magnets so as to regulate the current in the latter. In this way magnetic adhesion can be controlled at will. It is further claimed that an advantageous effect is produced by the pressure on the rails by the wheels, due to the attraction of the magnets. The electromagnetic brake clearly supplies a most important means for checking the speed of a car. Colonel Yorke describes it as "one of the most modern, and, when properly used, one of the most effective devices for controlling tram-cars."

The car had been recently overhauled, and was apparently in good condition. New brake blocks had been fitted to the driving wheels, the clearance being 1/16th of an inch when off. The driver stated that one of the sanders was

not in good condition, but there appears to have been some doubt on this point, in fact, the balance of evidence is that the driver was mistaken. The driver also stated that he had had trouble with his hand brakes previously to the accident, the wheels, he said, seemed to skid directly the brakes were applied, and, when released, did not immediately revolve even when sand was used.

It was a regulation of the company that all cars should be brought to rest at the top of the hill, but when the driver attempted to stop his car with the hand brake the wheels skidded, owing, as he said, to the rails being greasy from having been recently watered. Upon this he released the hand brake and tried the magnetic brake, but as the wheels continued to revolve the magnetic brake was useless, and the result was that the car ran past the Archway without stopping, and came on to the gradient of 1 in 22. The speed having increased so that the car was getting beyond control, the driver signalled to the conductor to apply his hand brake, but this having no effect the conductor released it again. The driver then reversed his motor, thus causing the automatic switch to blow, after which he moved the controller handle to the position in which the motors would generate current against each other in order to produce a powerful braking action. These efforts, however, had little effect on the speed of the car, which dashed down the hill with the terrible results before mentioned, until brought to rest by running into the empty car at the bottom of the hill. Before this the driver had jumped off, abandoning the car to its fate, his desertion being more disastrous as there was no one to ring the bell, a circumstance which in Colonel Yorke's opinion, led to the large number of persons being injured. The fact seems to suggest the need of an automatic continuous striking bell which would be put in operation only upon emergencies. This would have the additional advantage of relieving the driver of one operation at times when he would be hard pressed.

It will be gathered from what has been said that the electromagnetic brake is only brought into play when the motors are acting as generators, and therefore it evidently cannot be used when current is being supplied to the motors from the overhead conductor. The motors become generators through the action of the road wheels, and, therefore as soon as the latter cease to revolve the current required to energise the brake magnets ceases to be generated. This is the weak point of the arrangement, for if the hand brakes are put too hard on the wheels will skid or be locked, and the rail brake become useless. The loss of the assistance of the magnetic brake owing to the skidding of the wheels is more serious because the fact of skidding reduces very greatly the retarding effect of brakes upon a car.

The experiments made in 1878 on the Brighton Railway by Sir Douglas (then Captain) Galton, Mr. Stroudley, and Mr. Westinghouse are fairly well known to railway engineers. Apparatus was designed by Mr. Westinghouse by means of which, through water pressure and Richards indicators, there were recorded the retarding force which the friction of brake blocks exerted on wheels, the force with which the blocks pressed against wheels, and the force required to drag the van. These experiments clearly proved that when the wheels of a car are skidded, or blocked by the brakes, the retarding effect is very much less than when the brake shoes are pressed on the wheels with a force just short of that needed to cause skidding. The fact was known previously, indeed, in 1846 Mr. J. V. Gooch issued an order to the men on the South-Western Railway that wheels were not to be skidded, and the result might have been deduced from the experiments of Prof. Fleeming Jenkin on the effect of friction.

Although a skidded wheel does not afford the same resistance to the forward movement of the car as does one which continues to revolve, yet the brake shoes must be pressed on to the wheel with sufficient force to produce an effective braking action. This action is by far the most effective just at the instant that skidding commences, there being then a very sudden rise in tangential resistance. Just at the moment the brakes are released—the wheels being skidded—there is another rise in tangential force caused by the brake blocks. Prof. Fleeming Jenkin's experiments on the effect of friction at different speeds may be consulted with advantage in connection with these results. Although the ordinary brakesman does not carry out quantitative experiments by the aid of elaborate apparatus, he finds by experience that his brakes are most effective when the critical point is approached. The most skilled men will manipulate their brakes with great effect, getting the greatest retarding action for the car without skidding the wheels. The best way in which to work brakes, therefore, is to apply a considerable force at first, releasing it as the skidding point is almost reached.

Another point in connection with brake action, which almost follows from what has been said, is that although a good deal of pressure on the blocks is needed to make a wheel skid, a comparatively moderate force is needed to keep the blocks on when the wheels have once stopped revolving. Still another point bearing on the question under consideration is the decrease of friction that takes place with increase of speed of movement between rail and wheel. This is contrary to what is observed with lubricated surfaces but, as Sir Alexander Kennedy has pointed out, it bears out the smaller experiments of Prof. Fleeming Jenkin. On the Brighton Railway Company's trials the effect was clearly proved. The experimental van was drawn alone by a powerful express engine and was thus able to maintain a high speed with the brake on, and it was clearly shown that there was greater adhesion between rails and skidded wheels at high speeds than at low speeds. In some cases the tangential force diagrams showed a rise in adhesion of 100 per cent.

The bearing of these facts on the present case is plain. That a driver of a car will go as near skidding as possible is apparent, and an unskilled man will often pass the critical point. Then the wheels will cease to revolve and no current will be generated to energise the electromagnet, consequently the rail brake will be out of action, and, as a skidded wheel does very little to check the momentum of the car, all the elements of a serious catastrophe are present when descending any considerable incline. Beyond this the rail brake cannot hold a car stationary on a hill when once it has been brought to rest.

These defects would be overcome if the main current from the overhead conductor were available for energising the electromagnet. This would introduce some complication and extra fittings, but there does not appear to be any insuperable difficulty. The fact that the present electric-rail brake is liable to fail just when it is most needed—as shown by the Highgate tragedy—and the remembrance of the terrible results of a heavy car rushing down uncontrolled amongst traffic, make it plain that considerable sacrifice is warranted if the powerful rail brake can be brought more readily into play at a time when it is most efficient, namely, before the travel of the car has acquired a high velocity.

The particulars we have already of the accident form a practical illustration of the bearing of the experimental data collected on the Brighton Railway trials. Whether the skidding of the wheels of the car—which undoubtedly took place, as flats were afterwards found on the tread of the wheels—was due to want of skill on the part of the driver or to injudicious rigging of the brake is a matter of interest rather than importance, for drivers are as liable to be flurried or unskilful as brakes are likely to be improperly rigged. In regard to the first proposition, the driver's training in the present case consisted of eleven lessons of about one hour each in a school and twelve lessons on the road. This appears to have been considered sufficient instruction to entitle the driver to hold a certificate of "thoroughly instructed in the duties of a motor-man and now competent to take charge of a car." After that he had three days' practice on the Archway route with another motor man, including one day's instruction with the motor brake. He had been in regular work for twenty days at the time of the accident.

We are not aware whether this driver had had any mechanical training, or had been employed about the mechanism of motor vehicles before he began his driving career, but if not the course of instruction appears insufficient. This was borne out by his evidence at the inquest, for he was not aware that the magnetic brake

acted independently of the current from the trolley-wire, a fact quite sufficient to account for him attempting to apply the magnetic brake when the wheels were skidded In regard to the hypothesis that the accident was due to improper fitting of the hand brakes, Colonel Yorke says that the shoes, which cleared the wheels 1/16th of an inch, as stated, were new and of cast-iron The rubbing surface would therefore have the rough skin characteristic of iron castings, and friction would be greater than when the blocks had been worn smooth by use A very slight pressure would cause the wheels to skid, and as the springs which pull the brake off had only 1/16th inch compression, the brake might remain on after the driver had moved the brake lever to the release position The position of the brake blocks, in regard to the vertical component, may also have had an effect in keeping them on, as Colonel Yorke points out in his report The blocks were hung so that they would be below the centre of the wheels, and therefore the upward movement of the periphery of one wheel in each pair would tend to force the brake on when once it had made contact Colonel Yorke very properly condemns this arrangement, as it prevents the brakeman from using any nice adjustment such as is needed to prevent the wheel from skidding Sir Douglas Galton, in his paper before the Institution of Mechanical Engineers, recommends half an inch clearance between the wheels of a railway coach and the brake blocks, and it is usual in railway practice to place the blocks level with the wheel centres, or somewhat higher The nice adjustment of control needed for working hand brakes efficiently especially when rails are greasy, and therefore easily skidded is hardly possible with brake rigging such as was used The transmission was by a chain wound upon a spindle and through a series of rods and levers, "often roughly shaped to size and length in a forge, and connected by ill-fitting pins and joints, or by short lengths of chain" as the Board of Trade report states It is easy to understand that lost motion, due to such rigging, would account for a good deal of lag even if the gear were new

AN EDUCATIONAL GAP[1]

FOR many years past the attention of those who have been giving serious consideration to the complex educational problems which arise in this country has been directed to the gap which exists between the time at which pupils ordinarily leave the public elementary schools and that at which a very small proportion of them appear as students at our technical institutions and at various evening classes Many attempts have been made to bridge over this gap by continuation classes of various kinds and under various conditions, but these attempts cannot be said to have been successful in the past to any extent commensurate either with the importance of the problem or with the amount of care which has been bestowed upon it The causes of failure are deeply rooted in our social and economic organisation, whether we consider the large towns, the country districts, or the intermediate districts which are partly urban and partly rural In the large towns for instance, as soon as a lad is released from compulsory attendance at school, either by age or by the attainment of the necessary standard, his services have a market value which his parents are usually very unwilling to forego, though its immediate sacrifice may have an important effect upon the ultimate success of the youth in after life The consequence is that especially in London, large numbers of these boys take positions as van boys, errand boys and in similar occupations, in which for a few years they can earn wages up to or exceeding 10s per week By the time, however, that they reach the age of eighteen or nineteen they cease to be eligible for such work, and, not having utilised the intervening years since leaving school in attaining expertness in any skilled occupation there is no other course open to them but to join the ranks of unskilled labour, whence the step to those of the unemployed and unemployable is easy, especially, as they have reached the age at which their parents can no longer be expected to contribute to their maintenance In the country, other causes lead to somewhat similar final results

The inquiry of the consultative committee deals in great detail with one series of suggestions and experiments for bridging this gap for a minority of the pupils referred to. The particular problem minutely examined is that of providing slightly "extended facilities" (in a secular sense) for the best pupils, who would otherwise leave the elementary schools at the usual age of fourteen years or earlier, and whose parents would be subjected to the temptations mentioned above The question inquired into is how best to establish a type of school capable of educating such children, the parents being willing to maintain them for the necessary time, to a somewhat higher standard without trenching on the proper province of the secondary schools, on the one hand, or of the training which prepares specifically for a definite career on the other

The problem is one well suited for the consideration of the consultative committee on account of the wide and varied educational experience of its different members. To strengthen its hands, and to obtain the necessary information which might not be available within the four corners of its own membership, it has examined a carefully selected number of representative official and non-official witnesses, twenty-five in all For obvious reasons the names of the official witnesses are withheld, and therefore no names whatever are given nor is the evidence published in full, but ample quotations are made from it wherever they are deemed necessary and relevant to support the arguments of the report The only criticism one has to make upon the selection of the witnesses is that so few as five employers of labour can scarcely have had sufficiently varied individual experience to supply materials for dealing with so large a problem

That the present is a time of transition and experiment, and that the points of view from which educational problems are being attacked are rapidly changing, could receive no greater exemplification than is conveyed by this report The gradual change of the official attitude towards such problems has been very apparent to outside observers during the last four or five years in the different reports, prefatory notes to codes, and other official publications issued by the Board of Education from time to time This report deals in full detail with numerous points brought into view by the new standpoints, and it is to be hoped that the conclusions of the committee on these and cognate matters may be fully adopted by the Board in shaping its policy, without, however, rushing into opposite extremes

The swing of the pendulum from the time when "payment by results" was the fashionable official system has indeed been great and every page of this report bears evidence of the distance which has been travelled from those "dark ages" In point of time, however, the period referred to is sufficiently close to have left a legacy, which forms a factor in the present problem, in the shape of a body of teachers some of whom still find it difficult to realise that they are "freed from the trammels they have been accustomed to all their lives," and who have "a certain stock-in-trade which they think can be used anywhere"

The chief value of the report consists in the recognition, and some of the consequences of that recognition, of the proper function of education, in the root sense of the word, as a training of the moral qualities, the formation of habits of mind being regarded as more important than the acquirement of mere knowledge Prominence is given to the importance of the development of self-activity and resource, and powers of observation, the fostering of intelligence and interest in the work, and that training of the eye and the hand in conjunction with the brain which leads to "general handiness" These are some of the points dwelt upon, not once or twice, but many times and in varied aspects, in the pages of the report

The report also puts its finger upon some of the most glaring defects of the present and previous systems of education, both elementary and secondary The results, which have long been painfully evident to those who in any form have been entrusted with the further education of the pupils turned out, are that these pupils have not

[1] Report of the Consultative Committee upon Questions affecting Higher Elementary Schools. (Adopted by the Committee May 24, 1906, and issued, with a Prefatory Note, by the Board of Education, July 20, 1906.)

been taught "how to learn," that they are deficient in resource, in self-help, in curiosity of the right kind. In the majority of cases they are quite incapable of thinking for themselves, and in a large number of cases they cannot express their ideas, if they have any, in simple English. Such consequences necessarily follow from the old bad system of "payment by results" in the elementary schools, and from obsolete and defective methods of teaching, coupled with the worship of examinations, in the secondary schools.

The type of school proposed for filling the "gap," under whatever name it may be known, is one which aims at taking the best children of the elementary schools sufficiently early in their career to enable them to reach a somewhat higher standard of attainment than is aimed at in the elementary schools themselves. For good reasons which are set forth in the report, the age at which the change from the elementary school should be made is considered by the committee to be not less than twelve years. At this age the best pupils of the schools, selected by some simple qualifying examination combined with reports from the head teachers, are to be drafted into the new type of school. In this school the length of the course is to be three years, so that the pupils should remain there until they are fifteen years old. To ensure this it is felt that the parents of all pupils so transferred should be put under a moral obligation to maintain them at the school until the completion of the period, though it is recognised that it is not practicable to make the obligation a binding one in the legal sense.

The curriculum in the new type of school will differ within certain limits according to the needs of the locality in which it is placed, being different for (a) country districts, (b) the smaller towns of 20 000 to 50 000 inhabitants, and (c) large towns. Whilst specialised instruction such as is proper to the technical institute or the trade school is excluded, the aim of the school, in whichever of the above environments it may be placed, is to prepare the pupils more thoroughly for their life-work. Speaking generally, the curriculum is to consist (1) of what are usually classed as humanistic subjects, (2) of scientific and mathematical subjects, and (3) of manual instruction, with some physical training. In the humanistic section the English language and literature is to form the basis of the instruction, it being recognised that it is not possible to teach a foreign language effectively under the conditions, and Latin is of course excluded. History and geography are taken as subdivisions of the main subject. Class singing and religious instruction come under the same section, to which, on the whole, about one-third of the teaching time is to be devoted. In the scientific and mathematical subjects are included arithmetic, algebra and the principles of geometry, all as applied to practical calculations, account keeping as distinct from book-keeping, graphical methods of calculation, mensuration, and elementary natural science, with experimental work done by the pupils and varied according to the environment. To this group of subjects another third of the time is to be given. The manual instruction includes, for boys, general wood and metal work, treated from an educative standpoint, and aiming at the training of hand, eye, and brain, in addition there is definite instruction in drawing of the non professional kind, machine drawing, for instance, being excluded. For girls this manual instruction is replaced by training in domestic subjects and housecraft. Finally, about two hours per week are to be devoted regularly to physical training, which, of course, will differ not only as between boys and girls, but also in different localities.

One great difficulty in carrying out this scheme is that of obtaining the right kind of teachers. It is insisted upon more than once that what is important is the method of teaching rather than the matter. The ideal teacher, it is pointed out, should be a man of character and ability, with freshness of mind, thoroughly alive to the environment and thoroughly sympathetic with his pupils, he should be quite free from the old trammels which grew up in the dark ages referred to above. In which it will be remembered that the teacher who wished to rise to the higher posts in his profession was encouraged to pile certificate upon certificate in a great variety of subjects, in few, if any, of which, as results showed, was he really qualified to teach. Suggestions are made as to the training of these teachers, some of which appear to the writer not to be very practicable, more especially the suggestion that the teachers should spend one year in actual workshops. Apart from the difficulty of getting employers to be bothered with such men in their factories, the writer is of opinion that the year could be far more profitably employed in other directions, as the smattering obtained by so short an experience and so limited a view of commercial life is apt to be more harmful than useful. It is important to notice that the report emphatically recognises that for special technical subjects special teachers are required, but then these subjects are ruled out of the curriculum of the schools under consideration and, indeed, such subjects as shorthand, machine drawing, book-keeping, industrial chemistry and typewriting, some of which even modern schoolmasters are often inclined to view with favour, are set aside as unsuitable in any scheme of general education, whether secondary or elementary.

Considerations of space will not allow us to dwell upon many other important matters of detail which are handled in a masterly manner in this valuable report, suffice it to say in conclusion that it will well repay careful study, and certainly ought to be perused by everyone who is interested in the rapid developments which are taking place in the educational world.

R. M. W.

ELECTRIC TRAMWAYS

THE leading feature of the current issue (No. 180, vol. xxxvii.) of the Journal of the Institution of Electrical Engineers is the paper on the overhead equipment of tramways by Messrs. R. N. Tweedy and H. Dudgeon, especially in view of the fact that the overhead system has been so abused of late years by the general public, and thousands of pounds sunk in other schemes of electric tramways which might have been enormously reduced if the prejudice which exists against the overhead system on account of its supposed "danger" had been removed. The authors throughout the paper make a strong appeal for more economy in the capital outlay of tramway equipment, and show how in their opinion this may be brought about in the case of the overhead system.

Dealing with the size of pole to be employed, the authors are strongly of the opinion that we err seriously on the side of using too heavy and too strong poles, straining them too much, and consequently having larger span wire and more concrete for fixing than is necessary. Also they would do away with the usual cast-iron bases which protect the poles, as being not only a waste of money—being unnecessary—but also an actual source of danger, in that they prevent the pole within them from being painted when the outer portions are done—unless the box is lifted, a costly process—and allow water to accumulate inside the case, which causes the pole to rust badly.

The same remarks apply to the collars which it is customary to place round the joints in the poles, and water is liable to do much damage here also. If the bases are not done away with they must be ventilated and drained, so as to prevent the accumulation of water from sweating. The collars also must be drained properly. More economy is to be brought about in the trolley-wire itself, as in the authors' opinion too large a section is now being used, and they think that from 50*l.* to 80*l.* per mile may be saved on this charge alone. Again referring to the "hangers," the authors strike out strongly for the use of malleable iron in place of bronze and gun-metal fittings, which are so dear to some engineers—and are also dear in price as compared with malleable iron properly galvanised.

No local action takes place—with the malleable iron hanger—between the span wire and hanger as is the case with bronze hangers, and from experience iron hangers have been found to last longer than bronze or brass ones, though the oxidation of the iron bolts is one of the difficulties attendant on the overhead system. The authors suggest three methods of overcoming the difficulty:—

(a) The insertion of a shield between trolley-wire ear and the hanger to prevent the trolley wheels throwing

water up into the interior of the hanger—thus keeping the bolt dry—and "neither rust nor electrolysis can corrupt"

(b) A different form of hanger—simply a metallic link between the ear and span wire, and insulated by two or three independent external insulators

(c) The hanger to be composed of glazed porcelain with a plain metal bolt passing through, but the porcelain must be kept dry and sheltered from rain

Several other points of interest are touched upon by the authors, and the discussion which followed the reading of the paper by Mr Tweedy proved that the opinions on the points raised by the paper were very varied, and led to a keen criticism The idea of a shield was generally welcomed, and a suggestion was made that it should be manufactured in such a form as to be readily adjusted to existing hangers, without having to dismantle the same

On the subject of the strength of poles, however, the majority was against any reduction in size, and the question of the Standard Committee's "standard pole" provoked an animated discussion

The subject of the paper is one which for a long time has needed discussion, and the interest in it was shown by the fact that after the paper was read and discussed at the Birmingham local section's meeting it was re-discussed in London later in the session and we may hope that the many points and facts brought forward will help to mitigate the present existing difficulties of the overhead system, and at the same time help to reduce the capital expenditure on tramway schemes that may be undertaken by local authorities

SOME ASTRONOMICAL CONSEQUENCES OF THE PRESSURE OF LIGHT[1]

JUST a year ago Prof Nichols gave here an account of the beautiful experiment carried out by himself and Prof Hull which, with the similar experiment of Lebedew, proved conclusively that a beam of light presses against any surface upon which it falls Not only did Nichols and Hull detect the pressure which is difficult enough so minute is it, but they measured it with extraordinary accuracy, and confirmed fully Maxwell's calculation that the pressure on 1 sq cm is equal to the energy in 1 cubic centimetre of the beam

Thus we have a new force to be reckoned with It is apparently of negligible account in terrestrial affairs, partly in that it never has free and uninterrupted play But out in the solar system, where there is no disturbing atmosphere and where it may act without interruption for ages it may produce very considerable results Even here so minute is the force that it need only be taken into account with minute bodies Prof Nichols in his discourse told how it may possibly account for the formation of comets' tails if these tails are outbursts of finest dust To-night I shall try to show how it may be of importance with bodies which though still minute are yet far larger than the particles dealt with by Prof Nichols Such small bodies appear to abound in our system and to reveal their existence on any starlight night when perishing as shooting stars

We are to examine, then how the pressure of light or more generally the pressure of radiation, from one end of the infra red to the other end of the ultra violet spectrum will affect the motion of these small bodies

I think we get a clearer idea of the effects of light or radiation pressure if we realise from the beginning that a beam of light is a carrier of momentum that it bears with it a forward push ready to be imparted to any surface which it meets

Thus let a source A (Fig 1) send out a beam to a surface B, and to bring out this idea of carriage of momentum let A only send out light for a short time, so that the beam does not fill the whole space from A to B but only the length CD While the beam is between A and B B feels nothing But as soon as D reaches B B begins to be pushed, or it receives momentum in the direction AB and will continue to feel the push or receive momentum until C has reached B when the push will cease The existence of this push on B is definitely proved by the experiments of Lebedew and Nichols and Hull Now, unless we are prepared to abandon the conservation of momentum, this momentum must have existed in the beam CD and have been carried with it, and it must have been put into the beam by A while it was sending forth the waves A, then, was pouring out forward momentum, and was feeling a back push while it was radiating This back push against the source has not, I think, been proved to exist by direct experiment, though an indirect proof may perhaps be afforded by the case of reflection When a

FIG 1

beam is totally reflected, the push measured in light-pressure experiments is double that when it is absorbed, that is, there is a push by the incident beam and an equal push by the reflected beam and we may perhaps regard the reflected beam as starting from the reflector as source, and then we have a push back against the source But whether this be proof or not, I do not see how there can be the slightest doubt that the pressure against the source exists, and that for the same intensity of beam it is equal to that against a receiving surface

Some experiments which have been made by Dr Barlow

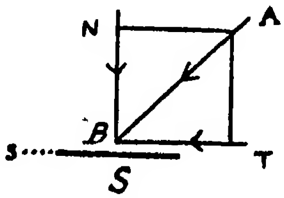

FIG 2

and myself appear to bring to the front this conception of light as a momentum carrier When a beam falls on a black surface it is absorbed—extinguished—and its momentum is given up to the surface In a beam of light AB (Fig 2) the momentum is a push forward in the direction AB, and if it falls on a black surface S it gives up this momentum to S The total push which is in the direction AB may be resolved into a normal push N and a tangential push T If S can move freely in its own plane, and only in that plane, T alone comes into play, and S will slide towards s

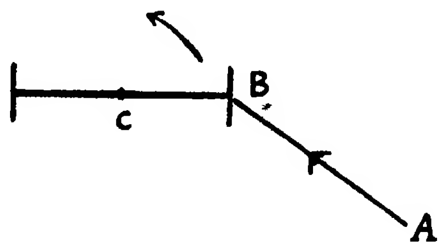

FIG 3

To show this effect we fixed two glass discs at the end of a short torsion rod hung by a fine quartz fibre the discs being perpendicular to the rod, and the face of one of them being blackened Fig 3 shows a plan of the arrangement The apparatus was enclosed in a glazed case, which was exhausted to about 2 cm pressure of mercury On directing a horizontal beam AB at 45° on to the black surface B the normal force merely pressed B back, but the tangential force turned B round the point of suspension C away from AB It is difficult to make the disc quite symmetrical and the beam quite uniform, and

[1] Discourse delivered at the Royal Institution on May 11, by Prof J H Poynting F R S

unless these conditions are fulfilled the disturbing forces due to heating of the surface, convection currents and radiometer effects may easily have a large moment either way round C. But these disturbing forces take time to develop, as Nichols and Hull showed, while the tangential push of the light acts instantly. Always when the beam is first directed on to B the motion in the first second or two is away from AB.

It has been urged that this experiment is not conclusive in that the lampblack is granular, and the force observed may be due to normal pressure against the sides of the grains. But if the back surface of the disc is blackened, so that the surface is much smoother, the action is as great.

Another form of the experiment which we have lately made is perhaps better. A horizontal disc of mica, about 2 inches in diameter, is suspended in the case by a quartz fibre (Fig. 4). The disc is blackened on its under face. If a beam of light AB is incident at 45° at B, it tends to push the disc one way round. The gas action due to heating may possibly and sometimes does, act against this push. But if an equal beam CB is sent from the other side instead of AB, the heating, and therefore the gas action, is the same, while the tangential push is in the opposite direction, and the deflection now is always less in the direction of the arrow than it was before, and the difference gives twice the effect due to the tangential push of either.

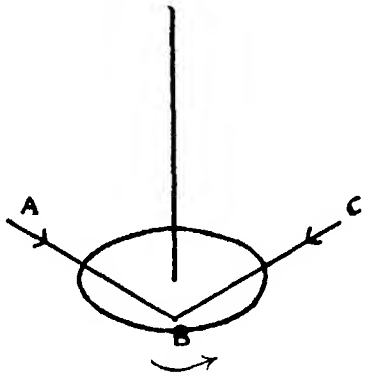

FIG. 4.

Another experiment, rather different in kind, even more clearly shows that light carries a stream of momentum.

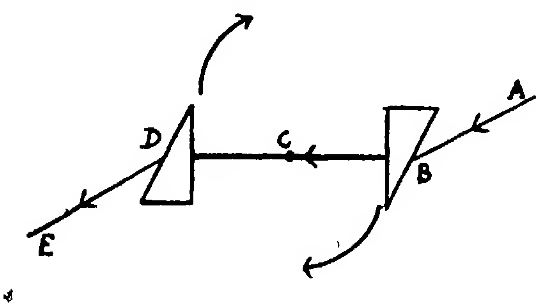

FIG. 5.

Two glass prisms BD (Fig. 5) were fixed at the end of a torsion arm and suspended by a fibre from C. A beam of light AB was directed horizontally so as to pass through the two prisms and emerge parallel to its original direction along DE. Always the torsion arm turned as indicated by the arrow, just as a pipe would tend to turn if it were bent as the beam of light is bent and carried a stream of water—a stream of forward momentum.

I will not now dwell on the interesting modification of the third law of motion which we must make to reconcile with it these experiments on light. It is enough to say that we must admit the luminiferous medium into momentum transactions just as long ago we admitted it into transactions with energy.

Let us now see how this way of regarding a beam of light leads us to expect a modification of the pressure when the receiving or the emitting surface is moving.

First, let us suppose that the receiving surface is moving towards the source. Let A (Fig. 6a) be the source. Let B be the receiving surface, moving towards A with velocity u. If B were at rest at C it would receive in one second the radiation and the momentum in length CD = U the velocity of light. But when a given wave starts from D, let the surface start from B and let them meet at the end of a second. Then B has evidently absorbed the momentum in length BD = U + u, and it has received more than it would have done if at rest in the ratio U+u : U. The pressure therefore is increased, and by the fraction u/U. It is easy to see from Fig. 6b that if B is moving away from the source it receives less momentum, has less pressure than if it were at rest, and the decrease is again by the fraction u/U. We may call this the "Doppler reception effect." "Doppler" since he was the first to point out the effect of motion on radiation.

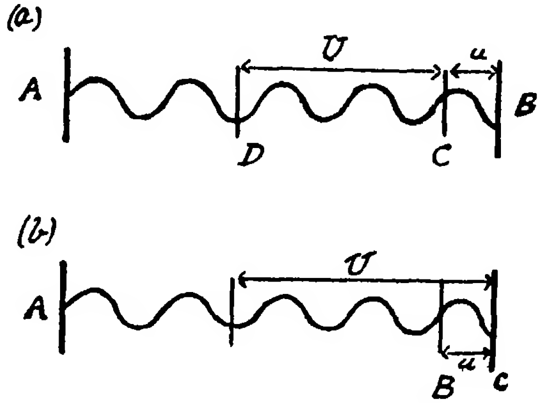

FIG. 6.

If the source is moving there is a nearly equal effect upon it. The pressure is increased if it advances and is decreased if it retreats, but the effect arises in a different way. It is now due to alteration of wave length. The source crowds up and shortens the waves it sends forward, putting into them more energy and more momentum, and so suffering an increase in pressure, while it draws away from and lengthens the waves it sends backward, putting into them less energy and momentum, and so suffering a decrease in pressure. The alteration of pitch produced in sound by motion of the source is familiar to all.

We can easily deduce the alteration in pressure if we make the reasonable assumption that the amplitude, the height or depth of the waves sent out from the source depends on its temperature alone, and not on its motion.

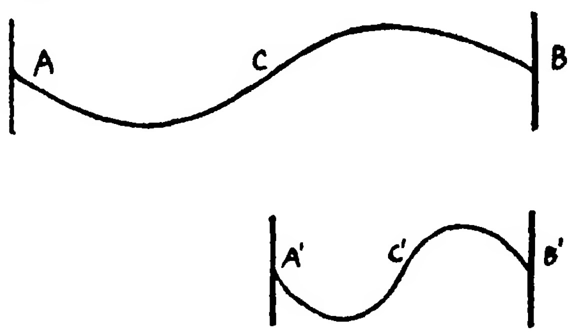

FIG. 7.

Let us imagine, by way of illustration, that the source moves with half the velocity of light, so that a wave which would be ACB (Fig. 7) is packed into half the space A'C'B'. With waves of the same height the energy in a

given length is inversely as the square of the wave length, so that A′C′B′ has four times the energy and momentum that ACB has *in the same length*, or the wave A′C′B′ has twice the energy and twice the momentum of the wave ACB sent out in the same time, and the pressure against A′ is twice that against A

When the speed of the source u is small compared with that of light, the increase of pressure in forward motion, or decrease in backward motion, is practically the fraction u/U (more exactly it is altered to $U/U \pm u$ of the value when at rest) We may call this the Doppler emission effect

Coming back to the pressure on a source at rest, that pressure depends on the rate at which the source is pouring out radiant energy, and that rate depends on the temperature of the source If the body is a black body or a full radiator, the rate of radiation is as the fourth power of the absolute temperature, a law no longer depending on precarious hypotheses, but the result of direct experiment Here is a table showing the energy radiated and the pressure back against the radiating surface at three important temperatures —

Radiation from and Back Pressure against a Radiating Surface

Absolute temperature	Energy emitted in ergs per second per sq cm	Back pressure in dynes per sq cm
0°	0	0
300° (Earth)	$4\ 3 \times 10^4$	$9\ 6 \times 10^{-6}$
6000° (Sun)	$6\ 9 \times 10^9$	1 5

A black surface on the earth, then, is pushed back with a force of 1/100 000 mgm per sq cm by its own radiation while the surface of the sun is pushed back with a force of a milligram and a half on the square centimetre This table helps us to realise the exceeding minuteness of the forces with which we have to deal

While we are considering the connection between radiation and temperature, it will be useful to see how the temperature of an absorbing particle depends on its distance from the sun Take first such a particle at the distance of the earth from the sun If the sky were completely filled with suns it would be at the temperature of the sun and give out the corresponding radiation But the sun only fills 1/200,000 of its sky, so that the particle only receives and gives out 1/200,000 of that radiation Its temperature is therefore $\sqrt[4]{200,000}$, say about twenty times less than that of the sun We can form a tolerably good estimate of the temperature of the particle since the rotation of the earth and its circulating atmosphere make its mean temperature, which is nearly 300° absolute, the same as that of the particle So that the temperature of the sun is probably about 6000° absolute or at any rate gives out as much radiation as a full radiator at that temperature

If we move the particle in to, say, one quarter the distance, a little within the nearest approach of Mercury, the heat from the sun is sixteen times as great, so that the temperature of the particle is twice as great, say 600° absolute, about the temperature of boiling quicksilver Out near Jupiter it will be half as great say 150° absolute, the temperature varying inversely as the square root of the distance

Now we have the data from which we can trace some of the consequences of light pressure in the solar system

The direct pressure of sunlight is virtually a lessening of the sun's gravitation for, like it, it varies as the inverse square of the distance As we can by direct measurement find, or at any rate form an estimate of the energy per c c in sunlight, we can calculate the pressure which sunlight exerts on a square centimetre exposed directly to it at the earth's distance, and it works out to about 0 6 mgm per square metre On the whole earth it is only about 75 000 tons, a mere nothing compared with the sun's pull, which is forty billion times greater

But if we halved the radius of the earth we should have one-eighth the gravitation, while we should only reduce the light pressure to one-quarter, or one would be only twenty billion times the other With another halving it would be only ten billion times as great, and so on until, if we made a particle a forty-billionth of the radius of the earth, its gravitation would be balanced by the light pressure if the law held good so far

This effect of diminution of size applies to the radiating body as well If we halved the radius of both earth and sun, the gravitative pull would be one sixty-fourth, while the light pressure would be one-sixteenth, or we should in each halving reduce the ratio of pull to push twice as much, and should much sooner reach the balance between the two, and, of course, the balance would be reached sooner the hotter the bodies. Thus two bodies of the temperature and density of the sun, and about 40 metres in diameter, would neither attract nor repel each other Two bodies of the temperature and density of the earth would neither attract nor repel each other if a little more than 2 cm, or just under an inch, in diameter

Suppose, then, a swarm of scattered meteorites 1 inch in diameter and of the earth's density approaching the sun Out in space their gravitation pull would be greater than their mutual radiation push, and there would be a slight tendency to draw together. When they came within 100 million miles of the sun radiation would about balance gravitation, and they would no longer tend to draw together As they moved still nearer repulsion would exceed gravitation, and there would be a tendency —slight, no doubt—to scatter

It appears possible that this effect should be taken into account in the motion of Saturn's rings if these consist of small particles Let us suppose that Saturn is still giving off heat of his own in sensible quantity, and, merely for illustration let us say that his temperature is about that of boiling mercury, 600° absolute Imagine one of a thinly scattered cloud of particles near the division of the rings At such a distance from the sun the particle will be receiving nearly all its heat from the planet, which will occupy about one-sixteenth of its sky If the planet filled the whole sky the particle would be at 600°, and give out corresponding radiation But filling only one-sixteenth of the sky it gives to the particle and the particle gives out again, only one-sixteenth of the 600° radiation It is therefore it $\sqrt[4]{1/16}$, or half the temperature, 300° absolute, the temperature of the earth Particles in the ring then about 1 inch in diameter would neither attract nor repel each other, and each would circle round the planet as if the rest were absent

Passing on from these mutual actions let us see how radiation pressure will affect a spherical absorbing particle moving round the sun We have already seen that the direct pressure of sunlight acts as a virtual reduction of the sun's pull and a small particle will not require so great a velocity to keep it in a given orbit as a large body will A particle 1/1000 inch in diameter, at the distance of the earth from the sun, and of the earth's density, will move so much more slowly than the earth that its year will be nearly two days longer than ours

In the second place we have the Doppler emission effect The particle crowds forward on its own waves emitted in the direction of motion, and draws away from those it sends out behind There is an increased pressure in front, a reduced pressure behind, and a net force always opposing the motion This force is a very small fraction of the direct sun push, in fact only $\frac{1}{2} \times \frac{\text{velocity of particle}}{\text{velocity of light}}$ of that push

But, unlike that force, it is always acting against the motion, always dissipating the energy The result is that the particle, losing some of its energy, falls in a little towards the sun, and moves actually faster in a smaller orbit The particle we are considering would fall in about 800 miles from the distance of the earth in the first year Next year it would be hotter, the effect would be greater, and it would move in further I think it would reach the sun in much less than 100,000 years. As the effect works out to be inversely as the radius, a particle an inch in diameter would reach the sun in much less than a hundred million years

There is another Doppler emission effect which must be mentioned If the whole solar system is drifting along

relatively to the ether, there is a Doppler resistance to the drift utterly negligible on the sun and planets, but quite appreciable on meteoric dust I confess that I am utterly unable to tackle the equations of motion when this force is taken into account, but if we make rough approximations it seems possible that it too would lead to a gradual approach to the sun The most obvious method of approximation in dealing with a small disturbing force is to omit it Let us adopt this method here, and turn to another effect which can be tackled—a Doppler reception effect, which only comes into play when a particle is changing its distance from the sun

Imagine a particle moving in an elliptic orbit to be coming towards the sun The sun pressure against it is slightly increased by the motion, or, virtually, gravitation is lessened When the particle has swung round the sun and is retreating, the sun pressure is slightly lessened, or, virtually, gravitation is increased That is, there is always a force tending to resist change of distance from the sun, tending, I take it, to make the orbit less eccentric, more circular

Now let us see how these forces will act on a comet, supposing a comet to consist of a somewhat thinly scattered cloud of particles of various sizes down to, say, a ten-thousandth of an inch in diameter Somewhat below that size the particles would be repelled and never tend to approach the sun at all, and would be weeded out of the comet as it first came into our system Let us suppose that, to begin with, the various sizes are well mixed up Then at once a sorting action will begin The direct sun pressure will lengthen out the year of the finer particles more than that of the coarser, and they will gradually trail behind in the orbit

Then the Doppler emission effect will gradually damp down the motion, again more markedly with the finer particles and they will tend to spiral in towards the sun and shorten the period of revolution Then the Doppler reception effect will tend to make the orbit ever less elliptic and again with the smaller particles the action will be more rapid

In any single revolution the effect will no doubt be small, even on the smaller particles, but after thousands or millions of revolutions the particles of different sizes may move in orbits so different that they may not appear to have any connection with each other In course of ages all the smaller particles, and if we have a sufficient balance in the bank of astronomical time even the larger particles, will end their course in the sun itself

There is one member of our system, Encke's comet, which at first sight looks as if it were manifesting these actions even in the short time, less than a century, that it has been under observation Its motion is commonly interpreted as a shortening of its period by 2½ hours in each revolution of 3⅓ years But Mr H C Plummer has investigated its case, and finds such difficulties, difficulties with which I need not now trouble you, that I fear the obvious explanation that the Doppler resistance is the cause must be abandoned But though we may not notice the effects in any short time, I see no escape from the conclusion that if comets are clouds of small particles brought into, and made members of, our system, they at once begin to undergo a sorting action, the finer particles drawing inwards more rapidly, and ultimately ending their career in the sun Possibly the Zodiacal Light is the dust of long dead comets

Where our ignorance is complete and unbounded hardly any supposition can be ruled out Let me, then, in conclusion, make one wild suggestion Suppose that a larger planet, still so hot as to be a small sun, succeeds in capturing a cloud of cometary dust Just the action I have been describing should go on The cloud would gradually spread into a long trail, the larger particles leading, the smaller dropping behind and moving in, and ultimately we might have a ring round the planet, a ring tending to become more and more circular as time went on, with the larger particles outside and the finer particles forming an inner fringe With different grades of dust we might have different rings Is it possible that Saturn has been wild enough to have adopted this suggestion?

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge —The special board for mathematics is now submitting for the approval of the Senate regulations for part i and part ii of the mathematical tripos embodying the resolutions which were adopted by Senate on October 25 It has been found necessary to make provision for the transition from the present system to the new one, and some temporary provisions are suggested for this purpose In other respects all the regulations now submitted have already been published in the draft regulations appended to the report above referred to It is these detailed regulations that the master of Sidney Sussex College and some other members of the Senate have announced their intention to "non-placet"

The observatory syndicate has been considering the great increase in astrophysical work which has been in the last few years carried on in the University observatory by Mr H F Newall It considers the time has come when an assistant of university standing should be appointed to assist Mr Newall, and announces the generous offer of Mr Newall to find 100*l* a year for five years toward the stipend of such an assistant The syndicate recommends (1) that for a period of five years, from January 1, 1907, there be appointed at the observatory an assistant, to be entitled "the assistant in astrophysics," who shall be under the general direction of the Newall observer, (2) that the assistant in astrophysics be appointed by Mr Newall with the consent of the Vice-Chancellor, and be removable in like manner, (3) that a stipend of 100*l* per annum, payable from the University chest, be assigned to the assistant in astrophysics Mr Newall having undertaken to augment the stipend by an annual sum of 100*l* for a period of five years from January 1, 1907

Two largely signed memorials have been presented to the council of the Senate The first urges (1) that a paper or papers in natural science shall be included amongst the compulsory subjects of any examination which may be substituted for the present previous examination, and (2) that in the classical part of such an examination no separate paper in Greek and Latin grammar shall be set The second requests the council of the Senate to appoint a syndicate to consider the advisability of instituting a diploma in architecture in view of the great importance of architectural studies which has already been felt in other universities, where such studies have been successfully organised

The following have been nominated examiners in the mechanical sciences tripos —Prof Hopkinson, Prof W E Dalby, and Mr C F Ingles, in State medicine Dr Anningson, Prof Nuttall Dr J Lane Notter, Dr R D Sweeting, and Dr A Newsholme in the diploma of tropical medicine and hygiene, Prof Nuttall, Mr C W Daniels and Mr W B Leishman

The board of agricultural studies, in consultation with the president of the Royal Agricultural Society, has appointed Major P G Craigie, C B, to be Gilbey lecturer on the history of the economics of agriculture for three years from January 1

A syndicate has been nominated to obtain plans and estimates for the extension of the Cavendish Laboratory on the site recently assigned it by a Grace of the Senate This extension has been rendered possible by the generosity of Lord Rayleigh, who has presented the Nobel prize to the University

Mr Aubrey Strahan, St John's College, has been approved by the general board of studies for the degree of Doctor in Science

A University lectureship in botany is now vacant by the resignation of Prof Seward The general board of studies will shortly proceed to appoint a lecturer to hold office from Christmas, 1906, until Michaelmas, 1911 The annual stipend is 100*l* Candidates are requested to send their applications, with testimonials if they think fit, to the Vice-Chancellor on or before November 30, 1906

Mr R P Gregory, of St John's College has been appointed senior demonstrator in botany until September 30, 1911

Mr A Hutchinson, of Pembroke College, has been

appointed chairman of the examiners for the natural sciences tripos, 1907

DR H E ANNETT has been elected to the newly-established chair of comparative pathology in the University of Liverpool

THE second award of the Vulcan fellowship in engineering of the Victoria University of Manchester will be made this session Applications should be made to the registrar on or before December 10 The fellowship which is of the annual value of 120*l* offers exceptional opportunities for research in engineering It is tenable for one year but may be renewed for a second, and in special circumstances for a third, year

THE *Times* states that the trustees of the late Mr T Graham Young have presented to the governors of the Glasgow and West of Scotland Technical College a sum of 10 000*l* to assist in making provision for the teaching of dyeing and bleaching in connection with the chair of technical chemistry in the college Mr Young's trustees have also voted a sum of 850*l* for the equipment of the laboratory for the chair

THE regulations for admission to the schools of mines at Clausthal and Berlin and to the mining and metallurgical department of the Aachen Technical School have been brought into unison Hitherto, at Clausthal and Berlin on matriculation twelve months' practical experience was demanded, whilst at Aachen no previous practical training was required Moreover, at Aachen the length of the course was three years, whilst at Clausthal and Berlin it was four years Henceforth no practical experience will be demanded for entry at Clausthal and Berlin, but on entering for the first examination students will be required to furnish evidence of six months practical work At Aachen the course will in future cover four years

THE London County Council has decided to expend 37,500*l* in acquiring sites for secondary school and training college purposes in the districts of Clapham Wandsworth North London and Tooting The schools are needed for the scholars elected under the council's new scholarship scheme It is proposed to erect six schools on the sites three for boys and three for girls and to adapt as a training college a mansion at present standing on one of the sites The cost of erecting the six schools will be about 160,000*l* and that of adapting the mansion 8000*l* It is anticipated that four more schools will be needed to provide for the full number contemplated by the scholarship scheme The total expenditure upon the council's proposals with regard to secondary schools is estimated at 575,000*l*

A MOVEMENT has been started for the reconstitution of Queen's College Cork and its conversion into a university centre for Munster Speaking at a meeting convened on Saturday last by the Lord Mayor of Cork and Mr McDonald chairman of the County Council Mr William O'Brien M P, said it is proposed to do in Cork what has been done in Birmingham The institution to be set up will be purely democratic It will belong to the people, and will be governed by the people's representatives The governing purpose of the university will be to open up a career in life to every gifted child in the province Mr O'Brien and his wife have decided to bequeath on their demise practically all their property as a contribution towards the endowment of a Cork University Mr O'Brien said it should be possible to arrange, if the borough and county councils of the province are willing to assume a temporary burden which will be an exceedingly slight one, and every shilling of which will be repaid at his and his wife's death, that a sum of 50 000*l* can be at once made available

THE recently published annual report on the work of the Glasgow and West of Scotland Technical College supplies as an appendix a report on a visit to American educational institutions, presented to the governors by Mr H F Stockdale the secretary and director of the college The subject of the director's inquiry was especially the equipment of the engineering schools visited, with a view to the economical and judicious expenditure of the grants made to the engineering departments of the Glasgow college Mr Stockdale insists that the only points where the superiority of American schools must be admitted are those in which the weight of money turns the scale The laboratory equipments are generally far more extensive and include more costly apparatus than is within the means of most British colleges The environment of certain American institutions, such as that of the University of Wisconsin and of Cornell University, is, too, a great advantage The director was much impressed by the facilities in the States for the study of railway mechanical engineering, and he points out that this seems to be a field in which the Glasgow college might do good work An Englishman in charge of a section of the metallurgical department of Columbia University alleged that many British students proceed to the States to study metallurgy Like other British visitors to America, the Scottish director saw and heard with envy the large number of able men on the staff in nearly all the best colleges in the States, and noted that the heads of departments are allowed plenty of time for research The circumstance that the large staffs make it possible for professors to engage in outside professional practice, to the advantage of the work of their colleges, is also commented upon Mr Stockdale has written a very useful report, which will repay attention from educational authorities

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, November 1 —Prof R **Meldola**, F R S, president, in the chair —A development of the atomic theory which correlates chemical and crystalline structure and leads to a demonstration of the nature of valency W **Barlow** and W J **Pope** The authors represent atoms in the combined state by "spheres of influence" An examination of the geometrical properties of closely-packed assemblages of spheres shows that the atoms of the elements must be represented by spheres of influence directly proportional in volume to their fundamental valencies, and that a closely packed assemblage built up of spheres of the appropriate sizes, so as to represent some particular compound, can be partitioned into units identical with the chemical molecule, and possesses symmetry and dimensions compatible with those of the crystalline substance In addition, it is shown that close-packed homogeneous assemblages of spheres possess other properties which lead to simple interpretations of multivalency and tautomerism and that ethylenic and acetylenic bonds and isomerism have complete analogues in peculiarities of homogeneous assemblages of spheres —Synthesis of carvestrene Preliminary notice W H **Perkin**, jun, and G **Tattersall** —Some derivatives of catechol, pyrogallol, benzophenone, and of some substances allied to the natural colouring matters W H **Perkin**, jun, and C **Weizmann** This communication contains descriptions of the preparation and properties of a number of new substances obtained at different times in connection with researches on the constitution of brazilin hæmatoxylin and other natural colouring matters —Experiments on the synthesis of the terpenes part ix the preparation of *cyclo*pentanone 4-carboxylic acid and of *cyclo*hexanone-4 carboxylic acid (δ ketohexahydrobenzoic acid) I W **Kay** and W H **Perkin**, jun —The hydrolysis of "nitrocellulose" and "nitroglycerine" O **Silberrad** and R C **Farmer** The hydrolysis is complicated by the simultaneous reduction of the nitric acid, and intermediate products are formed, which are gradually acted upon by the alkali these are practically insoluble in water and do not give rise to free acid when left in contact with water for several days —The acidic constants of some ureides and uric acid derivatives J K **Wood** In compounds which contain the grouping CO NH CO NH CO, there appears to be a mutual reinforcement of the imino-groups by the carbonyl groups present analogous to that exhibited by the carboxyl groups in succinic acid —The affinity constants of xanthine and its methyl derivatives J K **Wood** The results of determinations of the basic and acidic constants of xanthine, 7-methylxanthine, the three isomeric dimethylxanthines, and caffeine are described —The explosive com-

bustion of hydrocarbons, ii W A **Bone**, J **Drugman**, and G W **Andrew** The "inflammation" of mixtures of ethane or ethylene and oxygen has been studied In each case, steam, aldehydes, ethylene, and acetylene are prominent during the initial stages of combustion, whilst carbon is a later product —Contributions to the theory of solutions, i, the nature of the molecular arrangement in aqueous mixtures of the lower alcohols and acids of the paraffin series, ii, molecular complexity in the liquid state, iii, theory of the intermiscibility of liquids J **Holmes** —The relation between natural and synthetical glyceryl-phosphoric acids, part ii F **Tutin** and A C O **Hann** It is concluded from the results obtained that the natural and synthetical glyceryl-phosphoric acids are differently constituted mixtures of the α and β acids —Thiocarbonic acid and some of its salts Miss I G **O'Donoghue** and Miss Z **Kahan** The acid has the formula H_2CS_3 The salts are very unstable even in a vacuum —Studies in optical superposition, part ii T S **Patterson** and J **Kaye** The optical properties of di-*l*-menthyl-*l*-tartrate, di-*l*-menthyl diacetyl-*l*-tartrate and sodium *l*-menthyl *l*-tartrate have been examined —Optically active dihydrophthalic acid A **Neville** When the hydrogen strychnine salt of *trans* $\Delta^{2\cdot 5}$-dihydrophthalic acid is fractionally crystallised from alcohol, the acid is resolved into its *laevo-* and *dextro-*isomerides which are described

Entomological Society, November 7 —Mr F Merrifield, president, in the chair —*Exhibitions* —H J **Lucas** Photograph of *Panorpa germanica*, practically immaculate from Sutherlandshire, and a typical form for comparison, corresponding apparently to the *borealis* of Stephens Also a series of the genus to illustrate the range of spotting on the wings of both sexes —G C **Champion** A long series of a Henicopus (probably *H spiniger*, Duval), from El Barco, Galicia Spain to demonstrate the dimorphism of the females —H St J **Donisthorpe** Seven specimens of *Prionocyphon serricornis*, Mull bred from larvæ taken in the New Forest in July, live larvæ, and a larva and pupa figured, of the same, with a note on the species —Dr T A **Chapman** (1) A collection of butterflies, made in Galicia (lat 42° 16′ N, long 6° 44′ W) last July, including *Lycæna idas*, hitherto reported only from the Sierra Nevada, in the south-east of Spain (2) *L argus* (*aegon*) from the same district which though very close to the vars *hypochiona* and *bejarensis*, differed in a certain proportion of the specimens presenting the red of the marginal "peacock eyes" on the upper surface of the hind wings of the males —Hon N C **Rothschild** Branches of *Viburnum lantana* showing the mines of *Sesia andreniformis*, now discovered as the food plant of the species in Britain for the first time —F D **Jones** Two species of the genus Mollipa bred from Brazilian larvæ which were identical in form also photographs of the larvæ *in situ* —Dr F A **Dixey** A case of female Pierine butterflies to illustrate various conditions under which white pigment might be replaced by black He said that though melanism may occur as a sport it owed its establishment to the principle of selective adaptation —The **President,** mentioning a bug which Mr Cecil Floersheim had found very destructive to the eggs of *Papilio machaon* and *P asterias* said that it was remarkable to find one of the Heterotoma as a carnivorous species

Faraday Society November 13 —Dr F Mollwo Perkin, treasurer, in the chair —Some investigations relative to the depreciation of electrolytically produced solutions of sodium hypochlorite W P **Digby** This deals in the first place, with depreciation taking place in bottles of various colours in which dark amber bottles gave the best results the loss in 1817 days being about 40 per cent for a solution containing 4 216 grms of available chlorine per litre The corrosive action of hypochlorite solutions upon various metals is then discussed and the depreciations due to graphite, copper, zinc, lead and iron plates immersed in such solutions are set forth for a period of 480 hours A much greater depreciation takes place, due to galvanic action, when two dissimilar metals immersed in the liquid are connected by an insulated wire the paper gives records in the case of twenty-one different couples When iron is present as one metal in such a couple the depreciations are generally greater than for any two other metals —The Hermite electrolytic process at Poplar, C V **Biggs** This paper is a contribution to the data at present available on the subject of the electrolytic productions of hypochlorites It consists of a description of the plant in use at Poplar for the preparation of a solution containing about 4 5 grms of available chlorine per litre, for use as a disinfectant in the borough The author concludes that the magnesium hypochlorite, as made at Poplar, is sufficiently stable for practical purposes, and that it could be made in a warm climate without necessarily rapid deterioration —The electrochemistry of lead Dr A C C **Cumming**

CAMBRIDGE

Philosophical Society, October 29 —Dr Fenton vice president in the chair —The procession of *Cnethocampa pinivora* H H **Brindley** The processionary larva of this moth, one of the Eupterotidæ, which is common in the *Pinus maritima* districts of the Landes, marches in single file both in its nocturnal excursions from its nest in the pine to feed on the young leaves and also in the journey from the nest tree to pupate in the sand The primate spins a thread which is added to by the satellites in succession Fabre ("Souvenirs entomologiques," ser vi) describes many observations made in his laboratory near Avignon with imported families The author found a procession of 114 larvæ in the Cap Ferret Woods, Arcachon, on April 2, in the final procession for pupation Interruptions and rearrangements of the procession were made with results in the main in accord with Fabre's account, but in spite of much contact with bare hands the irritation from the poison hairs found by Fabre to be at a maximum in this stage, was not noticed Also the number of contiguous individuals removed was found to affect the mode of re forming the procession The procession was being attacked by a Tachinid fly, probably *Dexodes machairopsis* endeavouring to lay eggs in the larvæ and these seemed afraid of the hairs though one fly ran over the back of a larva and lanced it near the hind end As a rule a fly propped itself on the edges of its wings and faced the larva, pushing it with its legs as it passed, and apparently trying to insert its ovipositor ventrally between the pro podia Failures to insert the eggs seemed very numerous The larvæ evidently felt the lancing acutely always starting violently when it succeeded The intention to burrow seemed very little interfered with by interrupting the chain daughter chains started in different directions the primate soon burrowing in the nearest depression and disappearing in ten to fifteen minutes, while the satellites quickly followed his example The complete procession and the daughter ones made by interference, seemed to march towards the greatest sunlight —A note on a collection of Oribatidæ from British Guiana C **Warburton** and N D F **Pearce** Our knowledge of such microscopic land animals as the Oribatidæ rests almost entirely on European and North American forms because it is impracticable on scientific expeditions to collect individually creatures so minute It has been found however that moss or other material in which the mites live if packed in air-tight (preferably soldered) tins reach England from the most distant countries in such a satisfactory condition that the animals in it may be examined alive Some moss received in this way from British Guiana last June yielded a result which strikingly illustrates the importance of this method of collection About forty species new to science were found in it a fact the more remarkable in that the total number of satisfactorily established species of Oribatidæ previously known did not exceed 250 Some of the new forms are extremely interesting and will certainly necessitate a revision of the existing genera —The influence of spectral colours on the sporulation of various species of Saccharomyces J F **Purvis** and G R **Warwick** The light of a strong lamp was filtered through various coloured screens and played upon the surfaces of several species of pure cultures of Saccharomyces in an incubator at a definite temperature of 24° C to 25° C The results were compared with the effect of ordinary white light from the same lamp and also when the yeasts were allowed to sporulate in the dark but at the same temperature as the yeasts sporulating under the influence of the spectral colours of red green blue, and violet The conclusions were (1) red rays appeared to accelerate the formation of spores more quickly than white light (2) the green rays retarded the development of the spores (3) the blue and violet rays retarded

the development more than the green rays, (4) the violet and ultra-violet rays were still more effective, and they appeared to break down and disintegrate the vitality of the cells when the latter were kept for some time under their influence

PARIS

Academy of Sciences, November 12.—M. H. Poincaré in the chair.—Observations relating to equilibrium and reciprocal displacements between glycerol and other alcohols: M. **Berthelot**. The author refers to his experiments made between 1853 and 1862, and doubts the utility of the introduction of the words hydrolysis and alcoholysis.—A new and rapid method for the determination of the errors of division of a meridian circle: M. **Loewy**. A mathematical development of the method described in previous papers.—Some products of the fumerolles of the recent eruption of Vesuvius, with particular reference to the minerals containing arsenic and lead: A. **Lacroix**. The most abundant solid products of the fumerolles are those commonly found in all eruptions of Vesuvius, chlorides of iron, sodium, potassium, magnesium, and calcium, none of them well characterised from a mineralogical point of view with the exception of erythrosiderite. These chlorides are covered locally with realgar. The presence of galena has also been noted, the first time this mineral has been associated with the products of eruption of Vesuvius. Accompanying the galena were found magnetite, magnesioferrite, hæmatite, pyrrhotite, and pyrites.—Contribution to the study of the calorific emission of the sun: C. **Féry** and G. **Millochau**. A discussion of the results obtained by methods described in earlier papers. The measurements showed that there exists a distinct radiation outside the sun's disc, partly due to the dimensions of the thermocouple, but partly also to a calorific emission external to the solar image. On the assumption that the sun's nucleus acts as a black body, an attempt is made to correct the observed values for the absorption due to the solar atmosphere: the temperature obtained in this way lies between 5963° and 5888° absolute. The absolute error in the determination of a temperature in the neighbourhood of 6000° abs. is estimated to be of the order of 15°.—The photographic study of the telluric lines in the infra-red spectrum: Milan **Štefánik**. A description of observations carried out at the summit of Mt. Blanc. A comparison of two spectra obtained with a grating, one about noon and the other at 6 p.m.—Observations of the sun made at the Observatory of Lyons during the third quarter of 1906: J. **Guillaume**. The results are exhibited in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Groups of functions: Frédéric **Riesz**.—Differential equations of the second order and of the first degree the general integral of which is at fixed critical points: M. **Gambier**.—The relative value of standards of light, Carcel, Hefner, and Vernon Harcourt: A. **Perot** and M. **Laporte**. Taking the Harcourt lamp as unity, the Carcel is 0.996 and the Hefner 0.0931. The experiments brought out the difficulties inherent to the use of flame standards, and show the necessity of having an absolute standard as independent as possible of external conditions, such as the Violle standard.—The reduction of molybdic acid in solution by molybdenum, and the titration of reducing solutions by permanganate: M. **Guichard**. The brown solution obtained by the reduction of an acid solution of molybdic acid by molybdenum contains not a salt of the dioxide but a salt of the oxide Mo_2O_5. The conclusion is drawn that the dioxide of molybdenum does not form salts. The use of iron reduced from the pure oxide is recommended for standardising permanganate solutions.—The heat of combustion and of formation of some amines: P. **Lemoult**.—Xanthone and xanthydrol: R. **Fosse**. It is known that xanthone, although containing a ketonic oxygen, does not form directly a phenylhydrazone or an oxime. The reduction product of xanthone, xanthydrol, on the other hand, reacts directly with hydroxylamine and with semicarbazide.—The condensation of *o*- and *p*-nitro-benzyl chloride with acetylacetone: H. **Mech**.—The existence in Corsica of alkaline quartz porphyry, and a remarkable layer of orthose: M. **Deprat**.—The reproduction of the fig: Leclerc **du Sablon**.—The motor equivalent of resistant work in animal energetics: Jules **Lefèvre**.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 22.

ROYAL SOCIETY, at 4.30.—Studies on the Development of Larval Nephridia, Part ii. Polygordius: Dr. Cresswell Shearer.—The Structure of Nerve Fibres: Prof. J. S. Macdonald.—On Opsonins in Relation to Red Blood Cells: Dr. J. O. Wakelin Barratt.—On the Inheritance of Certain Invisible Characters in Peas: R. H. Lock.—The Influence of Increased Barometric Pressure on Man, No. 2: Leonard Hill, F.R.S., and M. G. Greenwood.—The Influence of the Kidneys on Metabolism: Dr. F. A. Bainbridge and Dr. A. P. Beddard.

ALTERNATING CURRENTS

***Alternating Currents** a Text-book for Students of Engineering* By C G Lamb Pp vi+325 (London Edward Arnold, n d) Price 10s 6d net

THIS book is designed to be a text-book for students of engineering, more particularly for those who are going through a course at the engineering laboratory at Cambridge In any attempt to write an account of alternating currents for such a purpose, the question arises at once, Out of all the materials at the disposal of the author, what should be selected as being most suitable, or on what principle should such a selection be made? The answer to this question may perhaps be best given by considering the requirements of engineering students Chiefly, perhaps, the mind must be trained to accurate thought, but, apart from this, which is common to all scientific education, a student should acquire a thorough knowledge of fundamental principles in such a way that he may have confidence in himself when he is faced with the various problems that constantly arise in the course of his professional career Beyond this, he should be taught sufficient of the methods of procedure in common use, so that when he takes up his first appointment in a subordinate position he will be able to follow with intelligence the methods of practice used by his superiors As Mr Lamb remarks in his preface, details of actual practice are unsuitable in such a book, and are best learned by actual contact with drawing-office work

If the book in question be examined in the light of these principles, it will be seen that the statements of the fundamental ideas are very clear, and are logically followed up It might, perhaps, be suggested that there is a tendency to explain various actions by means of equations rather than by physical conceptions One is somewhat reminded of the mathematical coach lecturing on optics, who introduced the subject of optical instruments with the remark that a telescope is defined by the equation K=0 Many students are naturally inclined to view physical problems in this way, and such a tendency should be checked, especially among intending engineers

With regard to the methods of procedure in common use, it cannot be said that this book is irreproachable In particular, practically no mention is made of the necessity of designing apparatus to meet a given temperature specification This necessity makes itself felt throughout almost the entire range of electrical apparatus, and yet with the exception of one brief paragraph the subject of temperature rise is not mentioned A student reading this book with no other source of information at his disposal might be excused for imagining that apparatus was usually designed without any definite ideas as to its capacity, and was only rated after it had been manufactured and tested to see what it would stand This must be regarded as an unfortunate omission

Turning now to the consideration of the book in detail, it should be remarked that a certain extent of previous acquaintance with elementary theory is assumed, chiefly the theory of magnetism, including hysteresis and eddy currents, and a knowledge of vectors The author has not attempted to introduce any symbolic treatment, no doubt very wisely

The first seven chapters cover the preliminary statements of the usual methods of treating alternate-current problems in general, also of measuring instruments, and discuss the theory of the single-phase transformer This piece of apparatus is regarded first of all in the light of a choking coil, for which the fundamental vector diagrams are obtained Following this the analytical expressions for an actual transformer are worked out, and methods are described whereby the regulation can be calculated The fifth chapter concludes with a paragraph giving a few constants for a modern type, which might have been more valuable if some indication had been given as to how such constants vary over a range of transformers for different outputs and frequencies, and with different load factors Special types of transformer occupy the sixth chapter, in which mention might have been made of sucking—or booster—transformers, to be quite up to date, while the seventh chapter is devoted to efficiencies

Apart from the points mentioned, which are not important, the foregoing chapters may be said to be excellent both in matter and in manner Unfortunately, the same cannot be said of the very brief mention of single-phase commutator motors which occupies the eighth chapter This part gives one the impression of having been put in as an afterthought, neither the repulsion motor nor the compensated repulsion motor is mentioned, and the type of series motor illustrated is already antiquated, moreover, the self-induction of the whole motor cannot be reduced to that of the field coils alone (p 95)

The rest of the book is devoted to the consideration of alternators both as generators and motors, and of induction motors Without following the treatment too closely, it may be remarked that wave forms are considered with reference to the presence of harmonics, the properties of concentrated and distributed windings are set out, and towards the end of the book armature reaction is considered in detail

The treatment of the latter subject is based chiefly on the method of synchronous reactance, in which the whole reaction is considered simply as due to a single internal self-induction This method has several drawbacks, and for practical work it is better to look upon the action of the armature as partly a demagnetising effect and partly a self-induction This treatment is very simple, and sufficiently accurate if proper constants are taken In chapter xxi of Mr Lamb's work the armature reaction is dealt with in greater detail, and is split up into three components, viz stray field reactance, cross and back reactances, each of which has its own magnitude and its own phase It is stated that this method leads to very good results, but it is more cumbersome, and seems to contain as much liability to error as the method above alluded to

Space will not permit of more than a brief reference to many of the subjects dealt with Induction motors are discussed with reference to the well known Hey-

land circle diagram, and emphasis is laid on the necessity for proper phase relations being maintained between the applied voltages A short chapter is devoted to induction meters, the principles of which are explained analytically and graphically

Compound alternators are referred to somewhat scantily, only two types being described both of which are manufactured by the Westinghouse Company The parallel running of alternators is examined by the aid of synchronous reactance and various methods of synchronising such machines are described

The operation of synchronous motors is treated in the same way at considerable length and an interesting graphical method is given for finding the value of the motor E M F for any given load, due, we understand to Mr G T Bennett of Emmanuel College, Cambridge There is a short reference to the hunting of such motors and to the action of the amortisseur The book concludes with a chapter on the rotary converter with special paragraphs on the E M F relations, current relations and ohmic loss, starting, pressure regulation efficiency and hunting

It may be remarked that no mention whatever is made of transmission lines a subject which would naturally be included in a book such as this, but possibly the author may have adequate reasons for the omission

Apart from criticism of the contents of the book, it is necessary to direct attention to one point referred to in the preface, viz the question of references to previous writers whose works have been requisitioned It is quite true that such references are not of great value to the student, and would be unnecessary for others if no original matter were introduced This however, is not the case, and it is unreasonable to assume that the learned persons, mentioned by Mr Lamb, who read the book will be acquainted with the authorship of this original matter The number of engineers who are practically familiar with all branches of alternating-current science must be very small, and anyone wishing to study a particular branch from Mr Lamb's book would naturally ascribe to him the credit for some of the original matter contained therein In a few places, contributions have been abstracted from the proceedings of learned societies without a word of acknowledgment Rather than adopt such a course it would be better to adhere to the system in vogue in Germany, where a man who writes a book on any subject without supplying with it a complete bibliography is considered a hopeless amateur

THE CELL AND HEREDITY

Die stofflichen Grundlagen der Vererbung im organischen Reich Versuch einer gemeinverständlichen Darstellung von Eduard Strasburger Pp viii+68 (Jena Gustav Fischer, 1905) Price 2 marks

THIS little sketch of the cell as the bearer of the hereditary qualities of the organism is full of interest, like everything that springs from Prof Strasburger's pen It is written in somewhat popular style, but is nevertheless a thoughtful and real contribution to the literature of the subject

The book opens with a brief but sufficient account of the processes associated with the formation of the sexual elements, and with the outlines of nuclear division in so far as they are necessary for the understanding of the main problem

The author follows current opinion in laying great stress on the qualitatively equal division of the chromosome secured by the mode of longitudinal fission of the chromatic thread and he regards the chromosomes themselves as permanent elements of the cell nucleus He explains in detail what is meant by "reduction-divisions," whereby the number of chromosomes in the sexual cells becomes reduced to one-half that characteristic of the nuclei of the body cells of the animal or plant This reduction is dependent on the circumstance that the paternal and maternal chromosomes, which at sexual fusion are contributed to the fertilised ovum, remain distinct in the nucleus of that and the succeeding cells which originate from it But at some period in the life-cycle certain cells all or some of the descendants of which are destined to give rise again to sexual elements exhibit two well-marked nuclear divisions that follow rapidly upon each other In this way a definite phase (termed by some writers the maiotic phase) is intercalated in the cellular life-cycle of the organism and it marks the transition from the cells with "unreduced" to those in which the nuclei possess the "reduced" number of chromosomes

The essential feature connected with the maiotic phase lies in the manner in which the reduction in the number of the chromosomes is effected Instead of a distribution to each nucleus of respective moieties of every chromosome taking place, as in the ordinary nuclear divisions, *entire* chromosomes first become temporarily united in pairs, and then the two members of each pair diverge from each other and, aggregating into two groups give rise to two nuclei each of which thus respectively contains half the whole complement of chromosomes present in the original nucleus

There is some divergence of opinion as to the exact method by which the association and subsequent distribution of the chromosomes is effected during the maiotic phase, and perhaps it may vary somewhat in different organisms, but there is a general agreement as to the final result

There exists a considerable weight of evidence tending to prove that the different chromosomes are responsible for different characters or groups of characters in the organism as a whole, and this circumstance is to be correlated with the fact that an equal number of these bodies is normally furnished to the fertilised ovum by each parent Each chromosome, therefore, which is derived from the one parent will have its homologue or duplicate originating from the other The importance of this becomes manifest when the facts of reduction are considered in relation to the behaviour of hybrids or crosses, in which a given character or group of characters (allelomorphs of Bateson) differs in the two parents When such

varieties are crossed, the character of one of the parents is commonly alone visible, but the (different) character of the other is really present, though latent, in the offspring. On again crossing the latter these latent characters reappear, and often in a very definite proportion, in this second generation.

This fact was discovered many years ago by Mendel, and has formed the basis of most of the recent experimental work that has thrown so much light on the problems of heredity. But although it harmonises, in a large number of cases, with the expectation based on a study of nuclear division, there are many things which still require explanation. Prof. Strasburger has touched on some of these, thus, for instance, the proportion of the sexes in many unisexual plants and animals is an almost invariable one, and appears to be inexplicable on the view of the chromosomes above indicated. On the other hand, we know, especially amongst animals, of cases in which the sex of the offspring can be definitely affected by conditions that are under control, although further study is necessary for their thorough elucidation. The assumption of entirely new characters again provides a field of research that is yet can hardly be said to have been explored at all except statistically, and it is at the same time one that is certain to yield most profitable fruit.

These and many other points are raised in the pages of a booklet which, while of small dimensions, is replete with material for thought. Prof. Strasburger has shown that a popular exposition does not necessarily connote a superficial treatment of a difficult subject.

J. B. F.

DISEASE AND ITS PREVENTION.

(1) *Immunity in Infective Diseases.* By Prof. Elie Metchnikoff. Translated from the French by Francis G. Binnie. Pp. xvi+591. (Cambridge University Press, 1905.) Price 18s. net.

(2) *The Inflammation Idea in General Pathology.* By Dr. W. H. Ransom, F.R.S. Pp. vi+354. (London: Williams and Norgate, 1905.) Price 7s. 6d.

(3) *The Milroy Lectures on Epidemic Disease in England. The Evidence of Variability and of Persistency of Type.* By Dr. W. H. Hamer. Pp. 72. (London: Printed at the Bedford Press, 20 and 21 Bedfordbury, W.C., 1906.)

(4) *Microbiologie Agricole.* By Dr. Edmond Kayser. Pp. xii+439. (Paris: Librairie J. B. Baillière et Fils.) Price 5 francs.

(1) PATHOLOGISTS will welcome this translation of Prof. Metchnikoff's great work on immunity, containing as it does the results of twenty years' work devoted to the subject. Commencing with some introductory remarks on the importance of immunity, the author passes on to review the phenomena of immunity in unicellular animals and in multicellular plants, the resorption of formed elements and of albumenoid fluids in animals, instances and mechanism of natural immunity against micro-organisms, the problems of acquired immunity against micro-organisms and of natural and artificial immunity against toxins, and the comparative immunity of the skin and mucous membranes to microbial attacks. A chapter on protective vaccinations, and another giving a useful summary of the whole subject and an historical sketch of our knowledge of immunity conclude the volume.

The dominant idea running through the whole book and supported with the greatest ability and ingenuity, is that the means of defence of the organism against the invasion of micro-organisms lie principally, if not entirely, with certain of the wandering cells of the body, "phagocytes," which comprise some of the leucocytes, and probably also certain endothelial and fixed connective tissue cells. These phagocytes either directly attack the invaders, enveloping and digesting them (phagocytosis), or in the case of toxins unite with these and prevent their toxic action, or secrete or produce as a result of their disintegration substances which are bacteriolytic and bactericidal for micro-organisms and occasionally antitoxic for toxins. Under natural conditions it is chiefly against the microbes and not against their toxins, that the organism has to defend itself, and hence phagocytosis normally is all important. It used to be supposed that the body fluids were bactericidal, and the blood serum *in vitro* frequently possesses marked bactericidal properties, but Metchnikoff and his co-workers, particularly Gengou, have shown that the blood *plasma* in such cases before coagulation has occurred is almost devoid of bactericidal power, but after coagulation the breaking down of leucocytes which accompanies this phenomenon apparently gives rise to the bactericidal substances in the *serum*.

There is little to criticise in the book. It is somewhat difficult to grasp exactly what cells Prof. Metchnikoff regards as phagocytic, as his nomenclature of the leucocytes differs essentially from that used by most pathologists. In the chapter on preventive inoculation Haffkine's anti-choleraic inoculation is criticised in a manner hardly justified in view of the excellent results shown by the statistics of Simpson and others. In certain places the statements are not quite up to date, since the book in the original was published in 1901.

The volume is fascinating reading, and anyone who first dips into it will in all probability do more and study it deeply. It forms a complete statement of the phagocytic hypothesis, and a masterly summary of the whole subject of immunity up to 1902.

(2) It is somewhat difficult to grasp exactly what the author of this book wishes to impart to his reader. Apparently it is his desire to formulate a conception of inflammation which shall be applicable to all organisms, animal and vegetable. The author believes that pathologists have always considered that inflammation is the first stage towards repair after an injury. But this is hardly so, it would be more correct to say that pathologists hold that the phenomena of inflammation *generally tend towards repair*, which is a conception distinctly different from that assumed by Dr. Ransom. According to him, an

injury in any organism is followed by responses misdirected and always damaging, "these misdirected perturbed responses are inflammation" . "It is distinguished from repair, for it is a perturbation thereof" This theme is supported by a number of examples, principally derived from injuries, &c, in vegetable organisms

(3) In these Milroy lectures Dr Hamer gives a brief but fascinating account of some of the plagues and pestilences that ravaged England and Europe during the early and Middle Ages, and attempts to unravel the nature of some of these That principally dealt with is the "sweating sickness," a mysterious disease which appeared in England in 1485, and recurred again and again By careful analysis this disease is proved to be epidemic influenza A consideration of the records of measles and of small-pox leads to the conclusion that these two diseases have maintained a wonderful fixity of character

(4) This book should usefully serve the purpose for which it is intended, viz to give an account of microbial activity in relation to agriculture The introduction on the morphology and classification of the bacteria is perhaps not altogether satisfactory, but the succeeding portions of the book successfully epitomise the subjects of nitrification and denitrification, the fixation of atmospheric nitrogen by the agency of various micro-organisms, and the various industries dependent on microbial activity Under the last heading the alcoholic, acetic, and lactic fermentations are dealt with at length, also bread and sugar making, ensilage, flax and tobacco manufacture, and tanning The book thus gives a very complete account of fermentation processes, is illustrated with a number of figures, and can be cordially recommended

R T HEWLETT

CAPTAINS OF CHEMICAL INDUSTRY

Some Founders of the Chemical Industry Men to be remembered By T Fenwick Allen Pp xxiii + 289 (Manchester and London Sherratt and Hughes, 1906) Price 5s net

THIS book consists of a series of biographical sketches of men whose claim to remembrance is mainly based on their connection with the development of the great chemical industry of Lancashire and the North, viz, the manufacture of alkali and of the other chemical products which are directly associated with that industry These sketches originally appeared in the *Chemical Trade Journal*, and Mr Allen has done wisely in putting them together and republishing them in book-form, and thereby rendering them more readily accessible to all who are interested in the personal history of technology

The book deserves to be in the library of every polytechnic and technical school in the country Although it deals with only a special branch of chemical industry, that branch, in point of magnitude and commercial value, is by far the most important of our chemical manufactures The story of its rise and progress, as illustrated by the biographies of its founders, is one of the most interesting and fascinating chapters in the history of industry in this country. Dr. Smiles has done much by biographical narrative to popularise what may be called the romance of industry, and it cannot be doubted that his works have served to fire the ambitions and to stimulate the endeavours of hundreds of earnest, thoughtful, young men. But the life-history of his heroes, and the story of their struggles, their disappointments and successes, is not a whit more marvellous or more enthralling than the stories of such men as Gossage, Gamble, Muspratt, Andreas Kurtz, or Henry Deacon No chemical technologist—be he young or old—can rise from the perusal of even the most meagre account of their life-work without realising that genius in chemistry is to be found as much in its applications to the material benefit of mankind as in the elucidation of its scientific truths

The men who collectively founded and developed in this country the several manufactures which are comprehended under what is known as the alkali trade sprang, for the most part, from the lower middle class They were persons of very small means, imperfectly educated, and with very little knowledge, to begin with, of chemistry It is difficult, indeed, in some cases to discover why they should have turned their attention to chemical pursuits Gossage was born in a small Lincolnshire town, Gamble was an ordained minister of the Presbyterian kirk in Enniskillen, Muspratt was also an Irishman—a rolling stone, who tried the army and then the navy, before he settled down to chemical manufacture, Deacon was a Londoner, and apprenticed to an engineering firm, Allhusen started life in the grain trade, and Peter Spence's father was a hand-loom weaver in Brechin, who apprenticed him to a grocer Not one of them was predisposed by the circumstances of his origin or home-life to take up chemistry, of which science, indeed, he could have no knowledge until long after the age at which most young men nowadays begin their life-work Deacon's bent may possibly have been determined by his association, as a boy, with Faraday, but it is more than likely that it was the failure of the engineering firm to which he was apprenticed that changed the current of his life and made him a glass-maker at St. Helens

However different they might be in temperament, in habits of mind, and in intellectual tendencies—it is impossible to conceive, for example, two more sharply contrasted characters than James Muspratt and Peter Spence—all the men had certain gifts in common, chief among which were imagination and invention, pertinacity and resource, courage and self-reliance Some of them, and not always the most talented, became wealthy; others, greatly daring, brought themselves to the verge of ruin in what seemed at the time heroic but hopeless struggles with the vagaries of a chemical process These men pursued chemical manufacturing with all the keenness of scientific investigation, and wrestled with difficulties for the pure love of conquest

Mr Allen tells the story of their hopes and disappointments, their failures and triumphs, and tells it very well We heartily commend his book to all who are interested in industrial progress, and in particular to chemical students who desire to know some-

thing of the personal history of those pioneers in technology who have been so largely instrumental in bringing one of our staple industries to its present pitch of development T E. THORPE

AIDS TO PHOTOGRAPHY

(1) *The Year-book of Photography for* 1906–7 Edited by F J Mortimer Pp 618 (London The *Photographic News*, 1906) Price 1s paper, 1s 6d cloth

(2) *The Photographic Picture Post-card* By E J Wall and H Snowden Ward Pp 104 (London Dawbarn and Ward, Ltd, 1906) Price 1s net

(3) *Magnesium Light Photography* By E J Mortimer Pp 88 (London Dawbarn and Ward, Ltd., 1906) Price 1s net

(1) THE present number is the forty-seventh issue of this hardy annual, and the amateur or professional photographer will not have much to complain about when he has entirely digested its contents In its present form it is a mine of photographic information, and contains data which are indispensable to every worker Thus there are useful hints for negative making and finishing, complete and up-to-date directories of the photographic societies of the United Kingdom, a collection of useful recipes, formulæ, and reference tables of general use for every kind of work

In addition to these and many other data which are valuable to the working photographer, there is a series of very interesting and helpful articles These have been written by such well-known men as Robert Demachy, Walter Benington, George E Brown, E J Wall, and others, and are on those particular subjects which have brought their names in the front rank Two full and very practical articles on bromide and gas-light printing are contributed by the editor, and these contain much that is new and useful to the practical worker

In fact, the volume should naturally find itself in the hands of every photographer, and is an indispensable book of reference Sixteen full-page illustrations on art paper accompany the text, and an excellent index completes the volume

(2) In this book the authors describe the making of picture post-cards from the initial sizing of the card down to the finished article The beginner should find no trouble in following the instructions laid out, for the authors have described the various manipulations in clear and concise language

Chapters are devoted also to photomechanical processes of producing a number of cards of one subject and to colouring post-cards, while part ii of the book deals with such information as how to publish the cards, how to sell rights of reproduction, &c Those who have a fancy for printing their negatives in this manner will gain some useful wrinkles by carefully reading this guide

(3) Mr Mortimer describes another phase of camera work which is as useful to the amateur as the professional Mr Mortimer does not let the worker take much for granted for in these pages he refers to nearly every kind of subject that may be met with, from a flower study in a studio to the stoke-hold of a warship The value of the text is very much enhanced by some excellent illustrations indicating not only the relative positions of camera, subject, and flash-lamp, but the actual results produced in these circumstances

Beginners and others will do well to read this book, which embodies the results of one who has had a very wide and successful practical experience in this branch of the subject

OUR BOOK SHELF

The Rusts of Australia, their Structure, Nature, and Classification By D McAlpine Pp vii + 349, plates, 55 (Melbourne R S Brain, Government Printer, 1906)

THIS book is published by the Department of Agriculture of Victoria, and represents the labour of many years on the part of the Government pathologist (vegetable) The first part, up to p 75, contains much useful matter, although, of course, only a summary of the work of others The second part is also necessary and useful, but contains some serious blemishes

The author records sixty-three new species, the majority of which are more or less unsound, being simply forms of the same fungus growing on different hosts, and when, as on pp 160, 165, the hosts have been incorrectly determined, the fungi have been given incorrect names The author does not err alone in this matter, but the better botanists set their faces strongly against this practice of naming parasites according to their hosts without any experimental inquiry as to whether the same fungus might not infest many hosts, as in fact they do in many cases, and can probably be caused to do in still more The seventy two rusts recorded in Cooke's "Handbook to the Fungus Flora of Australia" are now increased to 161, but it is difficult to say to what extent this merely represents records of previously known species on new hosts In some cases the new species are supposed to be distinguished by minute differences in the shape and character of the spores Yet on Plate xl, p 320 are figures of abnormal spores of one species giving a greater range than that which in others makes new species A good instance of the confusion which arises from the system of naming is given on p 169 where four names are inextricably entangled, and the author solves this difficulty by creating a name of his own, and so making matters worse for subsequent investigators

The coloured plates are good, with the exception of Plate i, which is useless for fungal diagnosis There are far too many photomicrographs, a few give verisimilitude to a paper and confirm the *bona fides* of the author, but good hand drawings are always better for reference if they can be relied on

On the whole, there can be no doubt that the book is a useful one A few typographical errors, such as Schelhammera for Schelhammeria, are unavoidable in a work of this kind, but our author is mistaken in supposing that the Kew index is an infallible guide in questions of synonymy and in the naming of species It would have been better, both from the scientific and economic points of view, if the work on which the book is based had been more experimental and less taxonomic in character Probably the author felt that owing to the amount of ground to be covered only a general review of it

could be attempted, which should serve as a foundation for further detailed investigations of the important questions connected with these plant parasites

The Dissociation of a Personality, a Biographical Study in Abnormal Psychology By Dr Morton Prince Pp x+569 (London Longmans, Green and Co, 1906) Price 10s 6d net

OF all the problems raised by the investigations of that section of modern psychology which deals with the abnormal and neurasthenic, those concerned with what is called multiple personality are perhaps the most interesting for psychology and philosophy as a whole Cases of multiple personality are comparatively rare and this book is of great value as being a very full and careful account of quite the most remarkable of such cases known to us Dr Prince had "Miss Beauchamp" under his care from the time when a second personality first manifested itself until "the real Miss Beauchamp" was at length discovered and restored It is the great merit of the book that the author abstains almost altogether from theories These he promises us in a further volume In this he contents himself with a careful history of the details of the extraordinary case Extraordinary it certainly is There were three distinct and entirely different personalities Of these, two known as B I and B IV, were alternating, and only knew of each other by inference Dr Prince evidently considers that they were caused by "the splitting up the original personality" and loss of memory due to an intense mental shock Not the least interesting part of the book is an account of the striking oppositions in what we should be inclined to call bodily characteristics manifested by those two personalities But the personality known as B II, or "Sally," is most interesting of all Not only did she exist as an alternating personality with B I and B IV, but she went on being conscious all the time, while B I and B IV were in possession of the body, with the difference that in the one case she was conscious, not only of outside events, but of B I's thoughts, while in the other she was aware always of what B IV said and did but not of what she thought The consequence is that the study of Sally throws light on many questions concerning subconscious personality, and such phenomena as dreams, hallucinations, &c The questions raised by the whole story in regard to how a personality is constituted, and what either an associated or a dissociated personality can mean, are many and important, but a discussion of the philosophical importance of the facts recorded here had better be postponed until the appearance of Dr Prince's promised second volume Meanwhile, the book can be recommended to all interested in questions of abnormal psychology The facts of the case are told in a very direct and interesting way

A D L

The "Lloyd" Guide to Australasia Edited by A G Plate for the Norddeutscher Lloyd, Bremen Pp 469+ix (London Edward Stanford, 1906) Price 6s

THIS compact handbook on Australia should prove of great service to tourists visiting the Antipodes The volume is profusely illustrated, and generously provided with maps and plans Great care appears to have been taken in making the information up to date The volume may not only be commended to travellers, but also to teachers of geography in secondary schools, who will find it useful as a supplement to their class-books

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Presence of Neon in Radio active Minerals

I HAVE for some time been engaged in a search for the rare gases, along with helium, in the radio-active minerals The earlier results were negative, but I have just found a trace of neon in two minerals—zircon and cyrtolite I cannot give definite quantities but should guess that the neon is not so much as 1/300th part of the helium

The separations have been made by Sir James Dewar's charcoal method He suggested this application of the method in his original publication of it

I cannot yet state positively whether or not the presence of neon with helium is general The manipulation has been progressively improved, and it may be that on repeating the earlier experiments on other helium-bearing minerals neon will be detected On the other hand, it may be that the presence of neon is connected with zirconia, for both of the above minerals contain it

R J STRUTT

Sunnyside Cambridge

Radium and Helium

IN NATURE of October 25 Prof E Rutherford has briefly restated the arguments for considering that radio-active phenomena are probably associated with atomic degradation, and that as a rule the loss of an atom of helium accompanies such changes the atomic weight of the substance undergoing transformation being diminished by 4, the atomic weight of helium

With this assumption, the transformation of the uranium atom (238 5) into radium (225) occurs owing to the loss of *three* helium atoms whilst the change of radium into lead (206 5) is due to the loss of *five* such atoms The numbers are not however in strict agreement with this view for 238 5, $3\times4=226\ 5$ instead of 225, and $225-5\times4=205$ instead of 206 5

This objection can, however, be removed by assuming that the atomic weight of radium is not 225, but 226 5, for we then have

$$238\ 5-3\times4=226\ 5$$

and

$$226\ 5-5\times4=206\ 5$$

The above assumption, that the atomic weight of radium is slightly higher than that obtained by Madame Curie in her latest determination, does not, indeed, appear improbable when it is remembered that the first determination of the atomic weight of radium by Madame Curie gave a value of 146 and that the atomic weight has become greater and greater as the material used has been more and more purified Madame Curie now considers that her latest value is correct to within a single unit, but she states that the material she employed contained a minute quantity of barium

Magneto-striction

IN your issue of March 24 1904 Mr Nagaoka gives an account of a lecture experiment on magnetostriction, a few weeks later Prof W S Franklin describes an experiment of the same kind Both experimenters use a vertical solenoid along the axis of which is fixed at its upper extremity an iron wire When a current is sent through wire and solenoid, the wire is twisted The explanation given is that the wire is magnetised helically, the expansion along the lines of magnetisation resulting in a twist of the free lower extremity

May not the result of the experiment be accounted for in the following way? When a current enters at a pole and passes out at the centre of a freely suspended magnet, the magnet rotates about its axis If, then, the current enters at one pole and passes out at the other—as both halves tend to rotate in opposite directions—one end of the magnet should be twisted relatively to the other

Photography in Natural Colours

IN NATURE of October 4 (p 571) you referred to the fact that the new method of photography in natural colours described by Prof Lippmann in the *Comptes rendus* of July 30 had been forestalled by myself and published in the *British Journal of Photography*, January 1, 1904 It is now my turn to disclaim priority, for Mr F Cheshire who wrote you on the subject before has just found, and kindly brought to my notice, a patent taken out by Mr F W Lanchester, of Alvechurch, dated 1895, which describes to all intents and purposes the same arrangement Not less curious is the fact that between the times of my own and Prof Lippmann's publications, another French investigator, M A Cheron, devised the same method and obtained a French patent for the same early this year, and another French worker M Raymond has according to M Cheron's communication to this month's number of *La Photographie des Couleurs*, been apparently working on the same lines

We have here, therefore the strange coincidence of five different people quite independently inventing the same method JULIUS RHEINBERG

16 Coolhurst Road, Crouch End, N November 24

ANTARCTIC EXPLORATION[1]

THE story of the Antarctic is longer in time than in materials, for the necessary existence of lands around the South Pole was affirmed by some of the earliest geographers There was abundant speculation about the character of these South Polar lands and the impossibility of reaching them before Bouvet found his islet and Cook was convinced of the existence of a great southern continent The Antarctic regions have furnished less dramatic incident and fewer commercial returns than the Arctic, but they have probably given, in proportion to the efforts devoted to them, more wide-reaching scientific results Dr Mill's book gives a full and graphic sketch of the whole subject It summarises the classical and mediæval speculations tells the narratives, and explains the results of all the expeditions that have worked in the Antarctic It handles the many branches of the subject—oceanography terrestrial magnetism topography and bibliography—with expert knowledge an intimate acquaintance with the scattered literature, and high literary skill The story is enlivened by pithy anecdotes and gives lucid explanations of the scientific problems, so that the book is as interesting as it is instructive It tells us for example of the cost of various expeditions Thus Cook's great results were achieved for 20,000*l* , and the *Belgica* Expedition gained its rich harvest for only 12,000*l* It helps us to place the explorers, by other incidents in their lives such as Dumont d'Urville's discovery of the Venus of Milo Maury's service in the Confederate Navy, Wilkes's achievements on behalf of the Northern States in the same war, and his famous arrest of the *Trent* The literary history is enlivened by many items of bibliographic interest, such as the mythical author "H M S Slaney," the recovery of the remarkable appeal to the Geographical Society in 1837 on behalf of Antarctic research by "A L ," from a French translation and the loss of Enderberg's MS in one of the London Society's libraries

The siege of the South Pole has been conducted by campaigns at three periods The first period began in the time of Drake, who reached 57° S lat and of de Quiros, who proclaimed his annexation "in the name of the Holy Trinity of all islands and lands which I have recently discovered and will discover even to the Pole " The great achievement of this period was the voyage of Cook, whom Dr Mill regards as the hero of Antarctic work He describes him as "the greatest of British maritime explorers, the one man who could be compared with Columbus and Magellan " He deplores that the only reward he received after his Antarctic voyage for "his stupendous service to science and his country, was a step in naval rank ", and he reminds us of the almost incredible fact that "Cook's own log was actually left unpublished for 130 years, while, incredible as it may seem, the description of some of the scientific collections of the voyage with the plates engraved at the time are only now appearing in the twentieth century " Cook's work showed that the Antarctic continent was confined within narrower limits than had previously been thought, but Cook, though he did not actually land on Antarctica, was emphatic as to its existence More definite knowledge of the Antarctic continent was obtained by the explorers of the second period that of Bellingshausen Weddell Biscoe, Wilkes and Ross It is to the work of that period that we owe most of the data that enabled Sir John Murray after the dredging of the *Challenger* had given the geological proof of the continental structure of the Antarctic lands, to prepare the outline map of Antarctica which as Dr Mill tells us, "subsequent discovery has not as yet materially modified " The active research of the second period was brought to a sudden and complete stop, the siege was raised for sixty years The abandonment of the work was perhaps partly due to the disgust at the quarrels in America over the Wilkes Expedition, and at the feud between Wilkes and Ross, but Dr Mill attributes it mainly to the concentration of attention in the Arctic, in consequence of the Franklin tragedy Ross's voyage naturally receives the fullest treatment, owing to its important results Great though they were they might easily have been greater for Dr Mill who has had personal experience of scientific research in naval vessels, remarks that "the average naval officer understands something of physical observations, but the collection of geological and natural history specimens is a mystery to him, and he abhors such mysteries ", and he describes how McCormick was hampered in his attempts to make zoological collections, and the misleading influence of Ross's theories, based on his mistaking records of pressure for deep-sea temperatures Had Ross's expedition says the author, "been organised on the lines subsequently followed on that of the *Challenger* the gain to science would have been enormous "

The third period includes the Antarctic research of recent years The long agitation for the renewal of the work is fully told by Dr Mill, from the appeal by Maury to the Geographical Society in 1860 and the persistent efforts of Neumayr, who was promised the leadership of an expedition from Hamburg in 1870 which was stopped by the Franco-German War, he records the "snubbed proposals " of the Australian colonies, the suggested Australian-Swedish expedition and the resumption of Antarctic research by the whalers, by Dallmann in 1873 the *Balaena* with W S Bruce in 1892 the *Jason* under Larsen and especially the *Antarctic* sent by Sven Foyn in 1894 to the Ross Sea These commercial enterprises re aroused the public interest in the Antarctic and led to the despatch of the British, German Belgian Swedish, and French expeditions of the opening of this century, the results of which are now in course

of publication Dr Mill closes his volume with proposals for an international scheme of Antarctic research, to be undertaken with the help of an international committee, the functions of which he proposes should be advisory He recommends the use of three or four whalers and light motor-cars, but no balloons, the uselessness of which has been twice proved The actual organisation of the expeditions should be left to those responsible for the money, and he holds that "the price of a battleship would conquer all the secrets of the South, not without risk, but still with far less risk than in say ten years of football" The book is illustrated with an excellent map of the Antarctic regions by Bartholomew, by many photographs of the scenery and ice-forms, and an excellent series of portraits of the chief actors in the Antarctic field The frontispiece, an instructive picture of Antarctic ice, has been contributed by Prof von Drygalski

through the pack to the latitude of 70° 25′ S., and though several times beset, it escaped and returned to the South Orkneys Suitable winter quarters were found in Scotia Bay, on Laurie Island; a house and magnetic observatory were built ashore, and the winter spent in active work On the return of spring sledging expeditions explored the island and determined the Ordovician age of its rocks by Dr Pirie's discovery of Pleurograptus and Discinocaris in the slates of Graptolite Island

As soon as the *Scotia* could be freed from the ice it sailed for Buenos Aires for stores, &c., while Mr. Mossman, with five men, remained at the station to continue the meteorological work. The *Scotia* returned on February 14, bringing with it a party of observers sent by the Argentine Government, which had wisely undertaken to maintain the meteorological station, Mr Mossman remained to help the Argentine party during its first winter, and the

The latest original contribution to Antarctic literature is "The Voyage of the *Scotia*," the narrative of the Scottish National Antarctic Expedition The expedition was organised and commanded by Mr W S Bruce, who after a voyage to the Antarctic in a Dundee whaler in 1892–3 had persistently advocated the despatch of an expedition to the Weddell Sea, and by careful training had rendered himself fit for its command He had made several visits to the Arctic, and from 1894 to 1896 had been in charge of the Ben Nevis Observatory, so that he was an expert in meteorological observation The funds available for the expedition were comparatively small, and were mainly due to the generosity of Mr Jas Coats, of Paisley The expedition left the Clyde on November 2, 1902, and the Falkland Islands on January 26, 1903. It was already late in the season, and the ice appears that summer to have been unusually thick in the Weddell Sea; but the *Scotia*, commanded by an experienced Arctic navigator, forced its way

Scotia left on February 21 with the rest of the Scotch expedition for its second cruise in the Weddell Sea

Here the expedition achieved its two great geographical successes It discovered a new land, Coats Land, which, judging from the boulders dredged off it, is composed of continental rocks, granite, gneiss, schist, sandstone, slate, and limestone This land is probably the edge of Antarctica, which therefore occurs 400 miles farther north than the position suggested for it on Sir John Murray's sketch map Murray had extended the Weddell Sea thus far to the south, as the natural inference from the reported soundings, which had been greatly exaggerated by Ross's primitive appliances Where Ross reported no bottom at 4000 fathoms, the *Scotia* found blue mud at the depth of only 2660 fathoms The *Scotia* has removed Ross's Deep from the chart During the return voyage the *Scotia* visited Gough Island, which was found to be volcanic, and after calling at Cape Town, Saldanha Bay, and various

Atlantic islands, it arrived back in the Clyde in July, 1904.

The narrative of the expedition is told by three members of the staff, Mr R C Mossman, the meteorologist and magnetic observer, Dr J H H Pirie, the medical officer and geologist, and Mr R N Rudmose Brown, the botanist Each author contributes the chapters describing the work with which he was most concerned The book perhaps suffers as literature from the difference in treatment of successive chapters, but it has the advantage of describing the whole expedition by the first-hand accounts of men concerned in all the different sections of the work

The narrative is of great interest It tells the story of long, thoughtful preparation, of the setting forth of a band of determined men, each well trained in his own line of work, and of their quiet, successful achievement of their purpose The expedition must be regarded, especially in view of its low cost, as remarkably successful Its discovery of Coats Land determined the hitherto quite unknown southern limit of the Weddell Sea, and has broken the longest unknown line in the coast of Antarctica As far as can be judged from published information, the *Scotia* will probably be found to have contributed more to Antarctic oceanography and biology than any of the expeditions in the field at the same time Its deep-sea equipment was excellent, and was fully used, and the description of the quantities of material obtained in the deep-sea hauls justifies the hope that the biological collections will yield most important contributions to our knowledge of the Antarctic fauna

SYNTONIC WIRELESS TELEGRAPHY

ON Tuesday evening, at a reception given by Lord Armstrong at the Queen's Hall, Sir William H Preece, K C B, F R S, being in the chair, a very important and interesting demonstration was given by Mr Valdemar Poulsen before a large audience, which included, among others, H R H the Duchess of Argyll, the Duke of Argyll, and the Danish Ambassador, of a new development of wireless telegraphy which affords grounds for hoping that the problem of syntonic signalling is at last nearing practical solution

Mr Poulsen will be familiar to readers of NATURE as the inventor of the telegraphone (see NATURE, vol lxii, p 371, and vol lxiv, p 183) Before describing the experiments shown at the Queen's Hall, it will be advisable to give a short account of the principles on which the new method is based It has often been pointed out in NATURE that all attempts hitherto made with regard to selective signalling are of a very unsatisfactory nature, and it has been suggested (NATURE, vol lxviii, p 249) that the solution is likely to be found in the application of the principle discovered by Mr Duddell in the "musical" or "singing" arc It is precisely that principle that Mr Poulsen has adopted The reason for this is sufficiently clear when it is considered that syntony, or tuning between transmitter and receiver, means the emission by the transmitter of sustained vibrations of definite frequency Only when these are produced is it possible to employ in the receiver a circuit tuned or resonating to this particular frequency

The main difficulty with all methods of spark transmission is to produce these sustained vibrations The signal produced by a spark discharge consists of a series of violent pulses each consisting of a short train of strongly damped vibrations of definite frequency Such tuning as can be done is accomplished by making the natural period of vibration of the receiving circuit the same as the vibration period of the individual pulses, but as the effect of the pulse itself as such is practically as great as that of its component vibrations, it will be readily seen that the tuning is only partial To make the syntonisation effectual, the effect of the pulse must be diminished and that of the vibrations increased In order to do this, the damping of the vibrations must be lessened until the signal is no longer a series of rapidly damped waves, but becomes a continuous succession of undamped, or, at the worst, very slightly damped vibrations, and the culminative effect of the continuous succession of waves will be far greater

The problem, therefore, reduces itself to the production of a train of undamped waves, and the manner of its solution was indicated by Mr Duddell when he discovered the phenomenon of the singing arc (NATURE, vol lxiii, p 182) Mr Duddell showed that if a continuous current arc, burning under such conditions that a small rise in the current is attended by a small fall of potential—or in symbols for which dv/dA is negative and numerically greater than the resistance of the shunt circuit—is shunted by a circuit containing self induction and capacity, there is spontaneously set up in that shunt circuit an alternating current the frequency of which is determined by the "natural" frequency of the circuit By the use of different inductions and capacities Mr Duddell produced alternating currents of various frequencies causing the arc to emit a musical note The frequency of these vibrations was, however, low—as is shown by the fact of the arc emitting a note—and in wireless telegraphy the frequency must be high Mr Poulsen has found that by burning the arc in an atmosphere containing hydrogen, by lengthening the

arc and by placing it in a strong magnetic field, the frequency can be enormously increased, and as many as a million vibrations a second may be obtained. Mr. Poulsen also finds that it is advantageous to have the anode of copper and the kathode of carbon, but when high currents are used the anode must be cooled by water running through tubes arranged for this purpose.

Mr. Poulsen showed several interesting experiments, illustrating the delicacy of the receiving circuit, in that on the slightest variation of frequency the activity of the receiving circuit ceases. Another experiment with a generator the oscillation circuit of which was connected directly to a resonator the frequency of which was in agreement with that of the generator circuit (about one hundred and seventy thousand oscillations per second), showed stationary oscillations with maximum tension at the top of the coil, and gave a peculiar soundless flame. As indicating the enormous amount of energy produced, Mr. Poulsen showed several experiments—lighting six incandescent lamps which were simply connected to a coil of wire which was brought near the oscillation circuit, destruction of a copper ring of wire when brought near, &c.

Turning to the transmitter used by Mr. Poulsen, there are two things of special interest, viz. the coupling and the signalling. As regards the coupling, the usual method employed is a very loose or close coupling, and the tuning is very sharp in either case. As regards the methods of signalling, various arrangements may be employed, but perhaps the most simple is by causing the key to short circuit a resistance periodically, which resistance must be large enough to reduce the amplitude and be included in the antenna-circuit. This method reduces sparking and permits of quick telegraphing. One may also telegraph by varying the tension of the magnetic field or of the feeding current, or altering the amount of hydrogen round the arc.

The receiving circuit for continuous waves includes an oscillation circuit with the least possible damping and in loose connection with the antenna-circuit. Owing to the continuity of the waves the detector may be arranged in such a way that it only intermittently forms part of the circuit of oscillation. Hence damping is avoided which the permanent inclusion of the detector would introduce. The apparatus which causes the intermittent contact is known as the "Ticker," and the usual material used for the contacts is either gold wire or German silver. Mr. Poulsen claims to be able to tune in practice to one per cent., and has received three messages simultaneously without mutual interference, the difference of wave-length in this instance amounting to three per cent.

Under the new method of undamped continuous waves Mr. Poulsen has sent a message from Lyngby, near Copenhagen, to North Shields, a distance of 530 miles, with a pole only 100 feet in height, for the expenditure of one kilowatt, and he hopes from this shortly to be able to get perfect communication across the Atlantic.

The chief advantages of Mr. Poulsen's system appear, therefore, to be:—(a) Extreme accuracy of tuning—thus ensuring selective signalling with no interference. (b) Freedom from interferences due to atmospheric electricity. (c) Greater efficiency due to accuracy of tuning and to the low potential of the electric surges impressed upon the aerial radiator.

Mr. Poulsen hopes that undamped and continuous wave-trains may yet be adapted to wireless telephony. The demonstration certainly proved that a great advance has been made in wireless telegraphy, and should the methods employed be brought into regular commercial use, there can be little doubt that Sir W. H. Preece's remark that probably the "death knell" of spark telegraphy has been sounded, will prove to be an accomplished fact. In the first place syntony will become a really practical affair, and interference troubles between neighbouring stations, which have to a certain degree been responsible for the necessity of international legislation, will disappear. Secondly, the cost of transmission will be diminished, as with undamped oscillations the energy used in transmission can be enormously diminished. For the same reason the effective distance over which messages can be transmitted will be correspondingly increased, and we may hope to see the real establishment of that Transatlantic communication so often announced and so often abandoned. J. L. M.

THE MARINE BIOLOGICAL ASSOCIATION AND INTERNATIONAL FISHERY INVESTIGATIONS.

LORD CARRINGTON, President of the Board of Agriculture and Fisheries, paid a visit to the Lowestoft Laboratory of the Marine Biological Association on Friday, November 23, in order to see the work which is being carried on at the laboratory in connection with the international fishery investigations in the North Sea. The principal features of the work were illustrated by means of a number of specimens and charts, which were explained by Dr. Garstang, the naturalist in charge of the laboratory, and by his assistants.

After being entertained at luncheon at the Royal Hotel by the council of the Marine Biological Association, Lord Carrington, who was accompanied by Mr. W. E. Archer, assistant secretary to the Board, visited the steam trawler *Huxley*, which carries out the investigations at sea.

Among those present to meet Lord Carrington were Mr. E. Beauchamp (M.P. for Lowestoft), the Mayor of Lowestoft, Mr. C. Hellyer (chairman of the committee of the National Sea Fisheries Protection Association), Mr. Deputy Sayer, of London, Mr. A. B. Capps and Mr. J. Jackman, of Lowestoft, and the following members of the council of the Marine Biological Association:—Dr. A. E. Shipley, F.R.S. (chairman), Prof. Bourne, Sir Charles Eliot, K.C.M.G., Dr. Harmer, F.R.S., Dr. Lister, F.R.S., Prof. D'Arcy Thompson, C.B., Dr. Chalmers Mitchell, F.R.S., Mr. G. L. Alward, Mr. J. A. Travers (treasurer of the association), and Dr. E. J. Allen (secretary and director), together with the members of the Lowestoft staff (Dr. W. Garstang, Mr. J. O. Borley, Dr. W. Wallace, Mr. R. A. Todd, and Mr. A. E. Hefford).

Under the present arrangement the scheme of international investigations terminates in July, 1907, but the council of the Marine Biological Association, in view of the importance of the work already accomplished, is urging His Majesty's Government to continue similar researches upon a more permanent basis. In this connection the following statement of the views of the council has been forwarded to His Majesty's Government:—

The council of the Marine Biological Association consider that the experience of the past few years justifies the opinion (1) that scientific investigations carried out on the deep-sea fishing grounds by means of a special sea-going steamer have produced results of great value concerning the biology of our food-fishes, (2) that a continuance of such experimental investigations is urgently required, in addition to the regular maintenance of market statistics and observations, in order to provide the exact knowledge necessary for the formulation of effective measures for the improvement of the supply of fish, and (3) that the advantages of international cooperation in

investigations extending over large areas are so great that it would be a decidedly retrograde policy that such cooperation should be abandoned. In support of the opinions expressed above, the council adduce the following statements and arguments with reference to sections (1) and (2) respectively, and believe that the statements will be fully substantiated in the detailed reports on the international investigations already published or in course of preparation.

(1) In conformity with the main object of British participation in the international scheme of investigations, as explained in the House of Commons by Mr. Gerald Balfour on June 12, 1902, and in accordance with resolutions of the International Council at Copenhagen in July of the same year, the investigations carried out in the North Sea by the association at the request of H.M. Government, have been largely concentrated upon the biological aspects of the undersized fish question, especially as concerns the supply of plaice.

By means of nearly 1000 hauls of the trawl the sizes of the plaice in different parts of the southern North Sea have been determined in detail and mapped out for different seasons of the year. The measurements of plaice recorded at sea on the S.S. *Huxley* exceed a total of 100,000. These investigations have clearly revealed the distribution of the various sizes of plaice in the English area during the period of investigation, and have contributed extensive material towards the collective report on this subject which is in preparation by the International Committee.

The causes which influence this distribution have been carefully investigated with respect to (1) depth, (2) nature of sea-bottom, (3) character of the food-supply, (4) growth, age, sex, and maturity, (5) locality of the nursery and spawning grounds, (6) seasonal migrations, (7) density of fish-population, and (8) intensity of fishing, and on most of these points definite results have been obtained.

By means of experiments with more than 7000 marked plaice the migrations of this species have been plainly traced in important areas, and much progress has been made towards the explanation of the observed movements.

The same experiments have furnished important results concerning the rate of growth in the chief parts of the English area.

An examination of the otoliths of more than 12,000 plaice caught and measured during the trawling investigations has yielded much new information concerning the age of plaice at different sizes on the chief fishing grounds, and has indicated a valuable method of controlling the results obtained from the marking experiments.

The marking experiments have afforded a new factor for estimating the intensity of fishing under modern conditions, and for measuring differences in this respect in different regions. In the case of medium-sized plaice (10–15 inches in length) we have found that out of 1100 fish of this size liberated at various seasons of the year in the southern area, where sailing trawlers predominate, approximately 30 per cent. have been recaptured within one year from the date of liberation, and that out of 400 fish similarly set free on the Dogger Bank and adjacent grounds, where steam trawlers predominate, about 40 per cent. have been recaptured in the same period.

The council regard these results as of great significance from a practical, as well as a scientific, standpoint, especially as there is reason to believe that the figures understate the full severity of the fishing.

Other results derived from the marking experiments and otolith investigations throw new light on the relative mortality of the two sexes, their habits of seasonal segregation, and their relative susceptibility to capture by the trawl, points which bear directly upon the problem of the effects of trawling upon the economy, and therefore the supply, of this species.

By the transplantation of large numbers of small marked plaice from the coastal waters to the Dogger Bank and other grounds, it has been found, during two years in succession, that the rate of growth is much greater on the Dogger Bank than on the nursery grounds, and the consideration of other factors renders it highly probable that the supply of fish can be profitably influenced by the transplantation of small plaice on a commercial scale.

A number of special experiments have been carried out on the *Huxley* to determine the vitality of trawl-caught plaice of different sizes. Owing to the variety of the conditions which influence the experiments, it is not possible at present to express these results in a single set of figures representative of average conditions, but the experiments support the opinions (1) that under commercial conditions of trawling on the nursery grounds a large proportion of the small plaice taken are mortally injured, and would not live if returned to the sea, and (2) that the beam trawl is less injurious than the otter trawl under similar conditions.

With respect to other food-fishes, such as cod, haddock, sole, turbot, &c., a complete register has been kept of the catch of the large commercial trawls on every occasion (between 900 and 1000 hauls), and about 250,000 measurements, exclusive of those of plaice, have been recorded. The information thus acquired has laid a broad basis of exact and trustworthy knowledge concerning the general features of the fish-populations of different fishing grounds, and concerning the size, weight, and to some extent the rate of growth of the various species represented.

This information has been supplemented by more than 700 experiments with fine-meshed nets and dredges for determining the character of the sea-bottom itself, the dominant features of the bottom fauna, and the distribution of the fish eggs and fry which escape the commercial nets. In particular cases experiments have been carried out on the migrations and rate of growth of marked fishes, especially of cod, sole, lemon sole, and latchet, and the relation of size to age in the case of cod and sole has been studied to a certain extent by means of otoliths. Extensive observations have been made upon the food of many species in different localities, and concerning their relations to one another either as prey, competitors, or enemies.

With regard to the hydrographic and plankton investigations specified in the international programme, the association has fully carried out its obligations in this respect by the most thorough and painstaking investigation of the waters of the English Channel. The results have been regularly forwarded for incorporation in the quarterly charts and records issued by the Bureau of the International Council, and have been reported on from year to year.

(2) In view of the fact that special research has been mainly concentrated hitherto upon the plaice, and that other valuable species present points of practical importance which still await solution, especially the sole, turbot, cod, and haddock, it is very desirable that the investigations which have been begun on these species should be continued and developed.

In this connection the council would point out that the necessity of scientific investigations has been generally recognised, whether such investigations be or be not carried out under a scheme of international cooperation.

While the council have indicated above the substantial progress which has been made with the experimental work at sea under their control during the past few years, they strongly urge that if this work should be brought to a sudden conclusion the prospective value of much preliminary labour and expense would be lost. Continuity of work is a factor of more than usual importance in experimental investigation of this character, not only because the conditions of the phenomena are constantly changing, but also because the extent and value of the results likely to be obtained are largely dependent on the experience of the staff employed.

NOTES

M. MASCART is retiring from the position of director of the Central Bureau of Meteorology in Paris. He will be succeeded on January 1, 1907, by M. Angot.

MR. L. A. PÉRINGUEY has been appointed to the directorship of the South African Museum, Cape Town, to fill the vacancy caused by the resignation of Mr. W. L. Sclater. Mr. Péringuey, who has been assistant director for some years, is a well-known entomologist and author of many papers on South African Coleoptera and other insects.

MADAME CURIE'S opening lecture to the students attending the course in general physics at the Sorbonne on November 5, on the subject of "Les Théories modernes relatives à l'Electricité et à la Matière," has been published in full in the issues of the *Revue scientifique* for November 17 and 24

DR E SYMES-THOMPSON, Gresham professor of medicine, and an authority on pulmonary diseases, died on Saturday, November 24, at the age of sixty-nine

SIR RICHARD FARRANT, who died on November 20 at seventy-one years of age, was treasurer of University College, London, which owes much to his business capacity It was largely due to him that the fund was started to raise 200,000*l* to provide for the necessary buildings and financial arrangements required for the incorporation of the college and the University of London, and his exertions in connection with the scheme will not readily be forgotten

THE New Zealand International Exhibition was opened on November 1 The exhibits are valued at three-quarters of a million sterling, and two thirds of this value represents industrial exhibits The exhibition is the largest that has ever been held south of the equator

THE winter meeting of the American Association for the Advancement of Science is to be held this year in New York City The first general session will be opened at Columbia University on the morning of December 27 The president of the meeting will be Dr W H Welch The sectional meetings will begin in the afternoon of the same day, and in the evening Dr C M Woodward, the retiring president, will deliver his address The meetings will be continued on December 28 and 29 and if necessary on December 31

VISITORS to the old Swedish cathedral and university town of Lund will find no little interest in the comparatively recent collections at the ethnographical museum illustrating many phases of rural life Old peasant houses have been taken down, brought from considerable distances, and set up at Lund, among the buildings being an old church and an inn Models of interiors of houses with costumed figures of inmates give an excellent idea of rustic conditions, reminding one, though on a smaller scale, of the Cecho-Slavonic museum in the Kinsky park at Prague No catalogue of the collections has yet been issued

IT is pleasing to note, from the current issue of its Bulletin, that the useful Société d'Encouragement, which is now in the 105th year of its existence, is in a satisfactory financial condition After several years of deficit, the accounts for 1905 show a substantial excess of income over expenditure The Bulletin contains useful summaries of recent progress in chemistry and mechanics, and affords clear evidence of the admirable work that is done by the society towards the development of the French national industries

THE Home Secretary received at the Home Office on November 22 a deputation of members of the Royal Commission on Coal Supplies, who asked that the records and estimates which they have prepared at great cost to the country should be kept up by the Geological Survey to prevent their labours from being almost abortive Lord Allerton believes that the whole of the information required could be had at a cost of 1000*l* or 1500*l* a year Mr Gladstone, while replying in sympathetic terms, pointed out that the Home Office is not properly equipped for cooperating with the work suggested, and he is afraid there may be difficulty in obtaining monthly returns. Lord Allerton, however, thinks that the difficulty is exaggerated, because, as chairman of a railway company, he has found that monthly returns can be obtained without increase of staff and without having to pay overtime.

IN connection with the fourth International Fishery Congress which is to meet in the City of Washington during September, 1908, a number of competitive awards has been arranged for the most important investigations, discoveries, or inventions during 1906, 1907, and 1908, relative to fisheries, agriculture, ichthyology, fish pathology, and related subjects The awards will be in the form of sums of money varying in amount from 12*l* to 50*l* The competition is open to any person, association, or company Papers may be written in English, French, German, or Italian The congress reserves the right to publish, prior to their publication elsewhere, any papers submitted in competition, whether such papers receive rewards or not The awards will be announced at a session of the congress All communications should be addressed to Mr Hugh M Smith, general secretary, United States Bureau of Fisheries, Washington, D C, U S A

AT the Institution of Mechanical Engineers on November 16 Mr Thomas Clarkson read an interesting paper on steam as a motive power for public-service vehicles The advantages of steam for public-service work were summarised as follows —the employment of a safe and cheap fuel, freedom from noise and vibration, absence of smell, and absence of change-speed gears, electric ignition, and friction clutch The maintenance cost of an engine that has been in regular public service on single-deck omnibuses for three years in Devonshire in 1905 was 6 23 pence per mile for total operating expenses, 1 5 pence per mile for tyres, and 1 16 pence per mile for depreciation Much has been done towards obviating mechanical stops and breakdowns during the past two years, and the steam omnibus of to-day is shown by Mr Clarkson to be a very satisfactory and trustworthy machine

IN the first article of the fourth number of the *Journal of Economic Biology* (vol 1) Prof A Nalepa, of Vienna, describes two "eriophyids" (Acari) from Fiji The first, *Eriophyes hibisci*, forms galls on a species of Hibiscus, of which the second, *Oxypleurites bisetus*, is also a denizen In the second article Mr G H Carpenter records the occurrence of larva of the chrysomelid beetle *Psylliodes chrysocephala* on cabbage-plants at Limerick Much damage was done to the cabbages on which the larvæ fed, but the author is of opinion that the occurrence is an unusual one, and that the normal food-plant of the species is different The third article is devoted to an account, by Mr R Newstead, of the life-history of the fly *Stomoxys calcitrans*, the larvæ of which are found in stables, cow-sheds, &c

IN vol xvii of *L'Anthropologie* appears an illustrated paper, by the late Mr E Piette, on evidence for the domestication or partial domestication of the horse (and possibly a wild ass) during the Reindeer epoch. This evidence consists of a number of sculptured and incised heads of horses invested with halters or head-stalls Some of these head-stalls, as shown in the figure of a head from the cave of St Michel d'Arudy, are of a very complex nature, consisting not only of several strands of rope, but of a piece of buck's horn or bone under the lower jaw The evidence seems to be conclusive as to the domestication of the horse

during the late Pleistocene epoch, and likewise demonstrates that, as might have been guessed, the head-stall is older than the bit.

THE cruciform brooches of Norway form the subject of a long article by Mr Haakon Schetelig in the second part of the "Bergens Museum Aarbog" for 1906 Prototypes of these ornaments occur in the peat of Nydam, and are believed to date from about 350 A D, and they are considered to have been introduced into Norway about the same time, since they are found there in graves containing weapons and implements of the Nydam type In a second article Mr O J Lie-Pettesen discusses the habits and etiology of Norwegian bumble-bees, more especially in connection with the powers of orientating their position and finding their way home The development of the crustaceans of the genus Sclerocrangon, and more especially that of *S ferox*, discovered in the North Atlantic by the Norwegian expedition of 1876–78, forms the subject of a communication by Mr Alf Wollebœk A striking resemblance exists between the development of Sclerocrangon and that of *Astacus fluviatilis*, which is remarkable considering the comparatively wide geographical separation of the two forms, and that one is marine and the other freshwater The concluding paper by Mr K Høye, deals mainly with the mould *Torula episoa*, affecting dried cod Tables are given showing the percentage of spores of this mould in various Norwegian localities, and measures are suggested for preventing its ravages on stores of the fish

LIEUT-COLONEL C D DURNFORD has a second paper on the flying-fish problem in the November number of the *Annals and Magazine of Natural History* As was noted in our columns at the time, the author in his original paper (published in the January issue of the aforesaid journal) endeavoured to prove on mathematical grounds that the "aeroplane theory" of the flight of these fishes was a physical impossibility, owing to the relatively small wing-superficies, and that consequently progression through the air must be due to intensely rapid wing vibration, aided in certain circumstances by movements of the tail, which in all cases give rise to the initial impetus In the supplementary communication Colonel Durnford adduces further evidence in favour of his explanation of the phenomenon Under average conditions, the chief features of the flight appear to be as follows —(1) the tail-impelled, visibly wing-assisted jump from the water to a height where the wings can work visibly, (2) the flight continued by an intensely rapid and laboured wing-movement, generally mistaken for a condition of rest, and, if seen at all, visible only as a blur, (3) short periods of slowing down of wing-movement, when the vibrations again become perceptible, (4) either sudden cessation of wing-movement, followed by an immediate drop into the water, or a short slow-down into visibility immediately preceding the immersion The result of careful dissection has been to demonstrate that flying-fish possess much greater development of the pectoral and caudal muscles than non-volant pelagic fishes of similar proportions

PROF C O WHITMAN has favoured us with a copy of an address (reprinted from vol v of the "Congress of Arts and Science, Universal Exposition, St Louis, 1904") delivered by himself on the problem of the origin of species It is argued that although Eimer's theory of orthogenesis and the mutation hypothesis of de Vries appear, respectively, to be contradictory to Darwin's natural selection, yet all three, in the professor's opinion may be reconciled Mutation may be admitted to be true in the case of the evening-primrose, but this by no means indicates that it occurs in most other instances On the contrary, the author affirms that he possesses conclusive evidence that species-forming variation advances in a definite direction (orthogenesis), although there are also variations advancing in different directions (amphigenesis) Orderly variation does not imply teleology, and the orthogenetic progress (of which we have an excellent sample in the development of the dark markings on the wings of pigeons) is the primary and fundamental one "In its course we find unlimited opportunities for the play of natural selection, escape the great difficulty of incipient stages, and readily understand why we find so many conditions arising and persisting without any direct help of selection"

ON the subject of the variations in the leaves of ferns grown in the sun or in shade, Miss J H M Ilroy publishes some notes on the leaves of *Nephrodium Filixmas* and *Scolopendrium vulgare* in the Proceedings of the Royal Philosophical Society of Glasgow, 1906 A marked difference was noted for two plants of Nephrodium with regard to the surface area of the leaves, that was twice as large in the case of the shaded plant as on the plant grown in direct sunlight, while the proportion was exactly reversed in the matter of spore output

THE Sea Island cotton produced in St Vincent continues to maintain its excellent quality Mr W N Sands, the agricultural superintendent, states in his annual report for 1905–6 that a considerable quantity realised nineteen and twenty pence per pound Owing to the refusal of planters in the United States to supply seed of this variety, St Vincent seed was selected to supply local needs and the requirements of other islands in the West Indies After cotton, cacao received the most attention, and nutmeg plants were also in request With respect to shade for cacao trees, the Madura *Gliricidia maculata* is preferred in St Vincent to Immortels, as being less liable to suffer from scale insects

MR E M FREEMAN, who has published previous papers on the fungus of *Lolium temulentum*, contributes a note on its affinities in *Annales Mycologici*, vol iv, No 1, showing that its continued existence in the grass is similar to the propagation of loose smut in wheat and barley Brefeld and Hecke have observed that a spore of the smut falling on the young ovary of these cereals can produce a mycelium, and later on spores from which germinating tubes pass into the developing embryo In Lolium spores are not formed, but the mycelium persists until the embryo begins to develop and then grows into it The author suggests that the evolutionary sequence in Lolium is later than that in the cereals on the hypothesis that spore formation has been prevented

THE "Agricultural Statistics of India for the Years 1900–1 to 1904–5" have been published in two volumes the first dealing with British India and the second with the native States The statistics have been compiled in the office of the director-general of commercial intelligence and may be regarded as a trustworthy record of the agricultural industries of India Running as the volumes do to more than 300 foolscap pages of figures, it is possible only to refer to one or two of the many interesting subjects included The tables dealing with the area under cultivation and total yield in the case of indigo show that from 1892 to 1900 the number of acres under cultivation was never under a million, and in 1894–5 was nearly a million and three-quarters During the same period the number

of hundredweights of indigo produced was never less than 112,000 and in 1894-5 reached 238,000 During 1905-6, on the contrary, the number of acres under cultivation fell to 381,000, and the amount of indigo produced to 45 000 cwt The case of cotton however is quite of a different character The number of acres under cultivation has steadily increased in recent years In 1899-1900 about 12 000 000 acres were planted, but during 1905-6 the number was well on the way to 21,000,000 The outturn in bales of 400 lb increased in a similar manner from 1 090 000 in 1899-1900 to 3 250,000 in 1905-6 The volumes certainly provide a rich storehouse of material for readers interested in Indian affairs

SEVERAL important papers appear in the October number of the *Journal of Hygiene* (vi, No 5) Dr Ashburton Thompson, President of the Board of Health New South Wales discusses the epidemiology of plague, particularly the part played by the rat and flea in its transmission, Prof Nuttall and Dr Graham Smith contribute an important and exhaustive account of canine piroplasmosis and of the morphology and development of the parasite *Piroplasma canis* Mr A T MacConkey describes the bacteriology of some cases of food poisoning which have come under his notice and Mr J D Thomson certain blood parasites of the mole An interesting instance of spirochatosis in mice is described by Mr C M Wenyon, and Dr Andrew Balfour gives some notes on herpetomonas parasites in fleas Finally the report of the commission for the suppression of ankylostomiasis in Porto Rico is abstracted The disease is very prevalent and probably 90 per cent of the inhabitants who number about one million suffer from it and are more or less incapacitated It is estimated that for an expenditure of 20 000*l* per annum 100 000 persons could be treated a year

IN the last volume of the Proceedings of the Institution of Civil Engineers (vol clxv session 1905-6 part iii) an account is given by Mr Baldwin-Wiseman of a series of investigations made by him during the last three years as to the relationship between the porosity of rocks and the flow of water through the interstices, under varying pressures A description and illustration of the apparatus employed also accompanies the paper The stones selected for experiment range from the Carboniferous to the Cretaceous rocks The stones were carefully selected and dressed into the form of cylinders 13 inches long and 6 inches in diameter These blocks were placed in a steel case and precautions taken to prevent any leakage The water was supplied from an hydraulic accumulator at varying pressures up to 75 lb on the square inch A drop of the piston which acted in the steel case of 1 centimetre was equivalent to a discharge of 62 06 cubic centimetres and the area exposed was such that a discharge of 1 cubic centimetre per second was equivalent to one gallon per hour per square foot of surface Special attention was given to the question of re soakage as bearing on the rate and amount of recharging depleted strata after a long-continued drought The results of the investigations are given in thirteen tables in the appendix to the paper where also there are two tables showing the geological formation, depth of wells, quantity of water pumped and other particulars of a large number of waterworks with details of the filter-beds

THE report of the Canadian Government Commission appointed to investigate the zinc resources of British Columbia and the conditions affecting their exploitation has been published by the Mines Department of the Department of the Interior (Ottawa, 1906) It forms a handsome volume of 400 pages, with numerous maps and illustrations In British Columbia the silver-lead ores occur in close association with zinc ore, which hitherto has proved a detriment to the value of the former The commission was appointed to arrive at a knowledge of the economic value of the zinc ores Mr W R Ingalls, an authority on zinc from the United States, was appointed to draw up the report, and Mr Philip Argall, of Denver, Colorado, and Mr A C Gardé, of Nelson, British Columbia, to act as his assistants Their report contains a vast amount of authoritative information on the mining and milling of zinc ores Some of the undeveloped zinc deposits of British Columbia are reported upon by Dr A F Barlow, of the Dominion Geological Survey The possibility of enriching the zinc ores of British Columbia to a high degree by magnetic separation is thoroughly demonstrated by the tests conducted by the commission In every case it has been possible to produce a zinc concentrate assaying upwards of 40 per cent of zinc and in some cases as much as 57 per cent of zinc Magnetic separators should be of the high intensity type, and means for roasting the ore are required The Blake electrostatic separator proved unserviceable for these ores which appear however, to be amenable to separation by flotation processes Electric smelting of the zinc ores is not advocated as this process must undoubtedly go through many stages of experiment before it can be pronounced a metallurgical and commercial success Smelting with Canadian coal is however quite feasible commercially Zinc ores are widely distributed and the situation is excellent for the creation of a zinc industry in British Columbia

AN interesting contribution to the study of pseudo-solution, dealing in particular with the colloidal forms of ferric hydroxide, is made by F Giolitti in two papers published in the *Gazzetta* (vol xxxvi ii pp 157 and 433) When ferric hydroxide, freshly precipitated by ammonia and thoroughly washed with water is examined microscopically it appears to consist of homogeneous gelatinous masses After being left in contact with water during several months, minute "nuclei" form in the gelatinous particles and on adding acetic acid the gelatinous portion dissolves leaving behind the nuclei" in the form of minute spheres of a nearly uniform diameter of about 7 μ These nuclei after being allowed to settle form with pure water pseudo-solutions which are characterised by being coagulable by dilute nitric acid A definite concentration of nitric acid necessary to produce coagulation corresponds to each concentration of the colloidal solution The pseudo-solutions of ferric hydroxide prepared by different methods have different physical and chemical properties, different solutions of the same concentration have for instance different absorption spectra With some solutions the addition of nitric acid causes the hydroxide to dissolve as nitrate, whilst with others a coagulation of the "hydrosol" is obtained With precipitated tungstic acid very remarkable phenomena are observed On washing the freshly prepared material very thoroughly with water, suspensions are obtained which after being left during several days, separate into a number of well-defined strata, differing in colour and degree of opalescence From these different strata pseudo-solutions can be prepared which at the same concentration have different limits of stability in presence of a coagulating agent such as nitric acid The explanation given of these phenomena is that the different pseudo solutions contain particles of different magnitude or molecular complexes

of a different character, the latter view appears necessary to explain the variation in chemical activity

IN the formula given in last week's NATURE (p 85) for converting Fahrenheit to centigrade degrees, the minus signs should have been plus, thus

$$C=(\tfrac{1}{2}+\tfrac{1}{2}\cdot\tfrac{1}{10}+\tfrac{1}{2}\cdot\tfrac{1}{100})(F-32)$$

Though the formula was incorrectly stated, the example given of its use showed plainly that a plus sign was intended.

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN DECEMBER —

Dec 3 3h. Jupiter in conjunction with Moon Jupiter 1° 58′ N
,, 10h 36m, to 11h 10m Moon occults ζ Geminorum (variable)
5 11h 15m Minimum of Algol (β Persei)
8 8h 4m Minimum of Algol (β Persei)
10–12 Epoch of Geminid meteoric shower (Radiant 108° + 33°)
9 6h Venus in conjunction with β′ Scorpii
13 2h Mercury and Venus in conjunction Mercury 0° 49′ N
,, 18h 1m to 19h 28m Transit of Jupiter's Sat IV (Callisto)
,, 19h Venus in conjunction with Moon Venus 2° 40′ S
15 Venus Illuminated portion of disc = 0 075, of Mars = 0 938
19 4h 40m to 5h 39m Moon occults γ Capricorni (mag 3 8)
,, 8h 32m to 8h 54m Moon occults δ Capricorni (mag 3 0)
20 13h Saturn in conjunction with Moon Saturn 1° 15′ N
24 3h 26m to 6h 26m Transit of Jupiter's Sat III (Ganymede)
25 Saturn Major axis of outer ring = 38″ 59, minor axis = 3″ 79
,, 10h 59m to 12h 12m Moon occults μ Ceti (mag 4 4)
28 3h Jupiter in opposition to the Sun
,, 9h 46m Minimum of Algol (β Persei)
30 8h 6m to 9h 37m Transit of Jupiter's Sat IV (Callisto)
31 6h 35m Minimum of Algol (β Persei)
,, 6h 41m to 9h 41m Transit of Jupiter's Sat III (Ganymede)

COMETS 1906*g* (THIELE) AND 1906*h* (METCALF) —Further observations of comets 1906*g* and 1906*h* are recorded in No 4134 of the *Astronomische Nachrichten* Prof Hartwig, observing at Bamberg on November 11, found that 1906*g* was of circular form with a diameter of 2′, having a central condensation 1′ in diameter and of the tenth magnitude On November 14 the condensation was very hazy and difficult to measure, whilst the total magnitude was about 9 0 Several sets of elements and ephemerides are published in the same journal, and the following is an extract from the ephemeris computed by Dr E Stromgren —

Ephemeris 12h M T Berlin

1906	α (true) h m	δ (true)	Brightness
Nov 30	11 8	39 1	
Dec 2	11 22	41 34	1 3
,, 4	11 38	43 59	
,, 6	11 54	46 14	1 2

Brightness at time of discovery = 1 0 (= mag 8 5)

The comet is now circumpolar, and apparently travelling in a line roughly parallel to, and south of, that joining ψ and χ Ursæ Majoris

Comet 1906*h* is so faint that it may only be observed with large telescopes

PHOTOGRAPHIC OBSERVATIONS OF GIACOBINI'S 1905 COMET —Some excellent photographs of comet 1905*c*, taken with the 10-inch Brashear doublet of the Yerkes Observatory by Prof Barnard are reproduced in No 4, vol xxiv, of the *Astrophysical Journal* That secured on December 29 1905 shows a great deal of structure in a tail 4½° long Joined to the comet's head by a narrow neck, this tail first broadens out and then narrows again its well-defined edges thus presenting a peculiar convex appearance The photograph taken on January 7, 1906, shows an even greater amount of structure a large number of thread-like strands diverging from a position about 1° from the head Although the tail of this comet was subject to great physical changes Prof Barnard considers that all the phenomena were due entirely to the solar action, there being no evidence of any outside distorting influence such as was suspected in the case of Brooks's comet (1903 IV)

SUN-SPOTS AND MAGNETISM —A retrospect of the stages whereby our present knowledge of the relation between sun-spots and terrestrial magnetism has been advanced at Greenwich is published in the *Observatory* (No 376) by Mr William Ellis For a long period Mr Ellis had charge of the magnetic observations at Greenwich and he describes steps of advance in which he took an actual part These observations were commenced at Greenwich and in several of our colonies, in 1840, and in September of the next year there occurred a considerable magnetic storm which was clearly shown to have commenced simultaneously in widely separated parts of the Empire thereby suggesting an external independent cause By the year 1852 General Sabine from a discussion of the collected results was able to suggest that this common cause was probably intimately connected with solar phenomena Mr Ellis proceeds to discuss the observations of both solar and magnetic phenomena, giving a number of direct references which should prove both interesting and useful to other observers

THE SOLAR ECLIPSE OF NEXT JANUARY —The Tashkent Observatory has issued a map of Turkestan showing the path of the moon's shadow during the total solar eclipse which will take place on January 13 1907 In the circular accompanying the map a series of meteorological observations is given, and these show that the prospects of a clear sky during the eclipse are not particularly favourable So far as is yet known three expeditions, one each from the Pulkowa and Hamburg Observatories and one from the Bureau des Longitudes are going to Samarkand (*Astronomische Nachrichten* No 4133)

NAKED-EYE OBSERVATIONS OF VENUS —In the November number of the *Bulletin de la Société astronomique de France* M A Benoit discusses numerous recorded instances of the crescent form of Venus having been seen by the unaided eye To determine the question of the probability of such an observation being possible a number of observations was especially made at the Juvisy Observatory during the period March–June 1905 Although on one occasion the observers thought they certainly saw the crescent subsequent examination with field glasses showed them to have been mistaken and from the complete discussion M Benoit concludes that this naked-eye observation is impossible

THE INTERNATIONAL CHART AND CATALOGUE —As the completion of the international scheme for charting the heavens is now within sight a correlated history of its inception and prosecution should prove of general interest Such an account is given in German, in No 48 vol v (new series), November 25, 1906, of the *Naturwissenschaftliche Wochenschrift* by Dr H Ludendorff and is illustrated by engravings of the instruments and a reproduction from a portion of one of the Potsdam plates

THE PERSEIDS, 1906 —In No 10, vol xxxv of the *Memorie della Società degli Spettroscopisti* Prof Zammarchi records the results of the meteor observations made on the nights of August 10–14 at the Vescovile di Brescia Observatory In all, 231 Perseids were observed and for the majority of these the paths brightness colour &c are recorded Many of the meteors left persistent trails and two of them apparently followed zigzag paths

RECENT EXPERIMENTS ON THE CRYSTALLISATION OF MINERALS

ALTHOUGH the crystallisation of alloys and of minerals must in its nature be essentially similar to that of the more ordinary solutions handled in the laboratory, the ranges of temperature and pressure involved are so far different as to make any experimental study a matter of considerable difficulty. In the case of the metallic alloys, the difficulties incident on the production and measurement of high temperatures have in recent years been overcome by the use of platinum-resistance thermometers, as in the investigation of the copper-tin alloys by Heycock and Neville, or by the use of thermal-junctions of platinum with a platinum alloy, as used so effectively by Roberts-Austen and his colleagues in the work of the Alloys Research Committee. As a result of these investigations, the conditions under which the different constituents separate from a liquid alloy, and the changes which occur as the solid ingot cools, are as fully known as the conditions which determine the separation of ice or salt from an aqueous salt solution.

The study of the crystallisation of an igneous mineral from a liquid magma has proved to be a task of very much greater difficulty. The temperatures of crystallisation are much higher, and frequently lie above the melting temperature of platinum; the minerals to be examined are not easily obtained in a pure state; they are poor conductors of heat and—perhaps the most serious difficulty of all—many of the minerals are so viscous when first melted that several minutes elapse before even the corners of the crystals become rounded; conversely, the melted materials often cool to a glassy mass and only reluctantly develop a crystalline structure. Difficulties such as these render almost inoperative the methods that have proved so effective in the study of metallic alloys; but new weapons have been provided by the perfecting of the radiation pyrometer as an exact method for the measurement of high temperatures, and by the commercial production of iridium melting at a temperature at least 600° above the melting point of platinum.

A quantitative study of the crystallisation of the lime-silica series of minerals has recently been published by Messrs. A. L. Day and Shepherd, of the Geophysical Laboratory of the Carnegie Institution of Washington (Journ. Amer. Chem. Soc., xxviii., pp. 1089–1114, September, 1906). The results they have obtained are so far in advance of anything that has previously been accomplished as to mark the opening of a new period in the development of experimental mineralogy.

Dealing first with the two pure substances from which this series of minerals is derived, it may be noted that lime melts at so high a temperature that it is not yet possible to make a satisfactory determination of the melting point; measurements can only be made with mixtures containing at least 20 per cent. of silica, and even these melt at temperatures ranging from 1400° to well over 2000° C. The melting point of silica lies below that of platinum, but the melting is so slow that when a charge of quartz was heated in an iridium crucible in an iridium tube furnace to the melting point of platinum (1709°) the grains did not coalesce, although they became tightly sintered together. Incipient melting could, however, be detected at a temperature nearly 100° lower, and the melting point is fixed by the authors at 1600° C.

Silica is a dimorphous compound, the two mineral varieties being known as quartz and tridymite. At temperatures above 1000° both quartz and amorphous silica change to tridymite. This is, therefore, the form which is stable at the melting point, and the melting temperature of silica is thus properly the melting temperature of tridymite, and not of quartz, as is commonly described. Occasionally by rapid heating quartz can be partially melted without inverting to tridymite, but it would hardly be possible by any known method to determine a separate melting point for unchanged quartz.

The converse change from tridymite to quartz is less easily observed. In presence of a catalyst, such as sodium tungstate, vanadic acid, or a mixture of potassium and lithium chlorides, amorphous silica was found to crystallise to quartz below 760°, and to tridymite above 800° by heating for five or six days the direct change of quartz to tridymite was proved at 800°, and from tridymite to quartz at 750°. The change is therefore reversible, and there is a true inversion point at about 800° C.

The melting-point curve for mixtures of lime and silica was explored by heating mixtures of definite composition, well mixed by grinding and repeated melting, on a platinum or (for higher temperatures) iridium strip, and noting the order of fusion. In this way two maxima and three minima were found, and these were subsequently investigated in such a way as to determine the exact composition and temperature at which each occurs. The maxima at 48 per cent. and 65 per cent. CaO correspond with the composition of the metasilicate $CaSiO_3$ and the orthosilicate Ca_2SiO_4, but no indication could be obtained of the separation from the melt of the compounds $2CaO.SiO_2$ or $3CaO.SiO_2$, or of the silicate $4CaO.3SiO_2$ analogous to the mineral akermanite.

Both the metasilicate and the orthosilicate are poly-

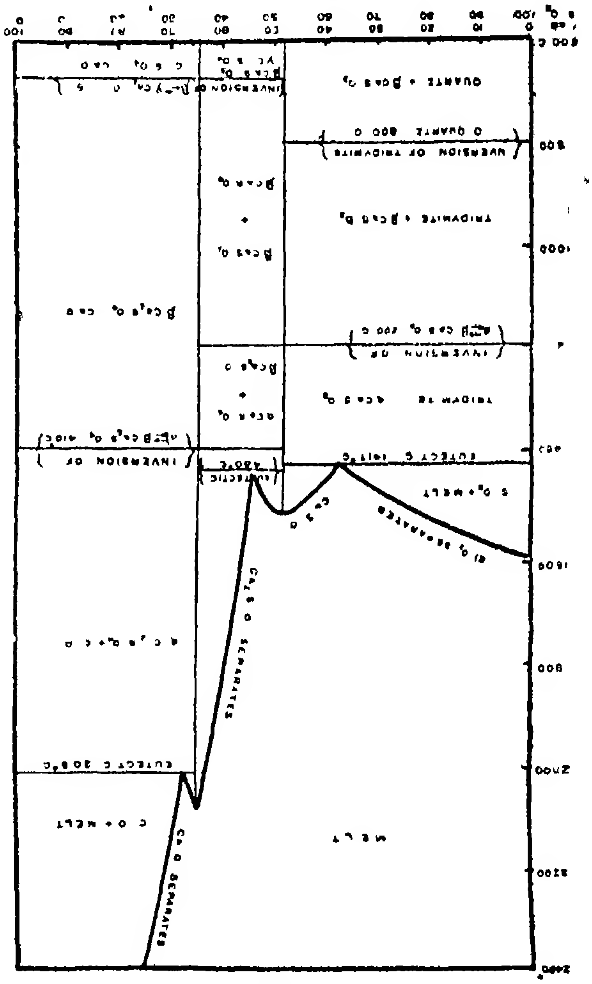

FIG. 1.

morphous. The metasilicate crystallises at 1512° in a pseudo-hexagonal form, and inverts at 1200° to a form identical with the mineral wollastonite. The orthosilicate crystallises at 2080° in a monoclinic α-form of density 3.27, and inverts at 1410° to an orthorhombic β-form of density 3.28, and again at 675° to a monoclinic γ-form of density 2.97.[1] The latter change involves an expansion of 10 per cent. in the volume of the substance, and is thus responsible for the disintegration or "dusting" of the orthosilicate and all mixtures containing more than 51 per

[1] It is unfortunate that the authors have reversed the convention which obtains in the case of iron, whereby the γ form is that which is stable at the highest temperatures, and the α-form that which is stable at atmospheric temperatures.

cent CaO. The orthosilicate is readily attacked by water, which dissolves out the lime in large quantities, this is probably the reason why it is not found as a natural mineral.

The three eutectics are —(1) tridymite+metasilicate, 37 per cent. CaO, 1417°, (2) metasilicate+orthosilicate, 54 per cent CaO, 1430°, (3) orthosilicate+lime, 67½ per cent. CaO, 2015°

Although the melting point of lime is unknown, the authors have been able to plot a complete diagram of the different equilibria that may occur in this series of compounds (Fig 1) The importance of such an achievement can scarcely be overestimated, and there can be little doubt that it will play as important a part in the development of experimental mineralogy as Roozeboom's classical diagram for the iron-carbon steels has done in modern metallurgy

T M LOWRY

CHARACTER AND CAUSE OF SUN-SPOT SPECTRA[1]

IT is now just forty years since the selective widening of Fraunhoferic lines in sun-spot spectra was first observed by Sir Norman Lockyer Since then various papers relating to the same subject have been published by Sir Norman Lockyer, Prof Young, and—more recently—Dr Mitchell and Prof Hale

The authors of the present paper state at the outset that in considering the chief features of sun-spot spectra, three points especially attract attention —

(1) The fact that certain lines in the spectrum of a given element are strengthened, others are weakened, the remainder being unaffected

(2) The occurrence of the strengthened lines in the visible spectrum only, none appear in the ultra-violet

(3) The relatively great intensity of the continuous back ground of the spot spectra in the less refrangible region

From what is known of laboratory spectra taken under varying temperature conditions, the following facts accrue —

(1) That in passing from a high temperature to a lower one, certain lines are relatively strengthened, some are unaffected, and others are diminished in intensity

(2) That such a reduction of temperature is accompanied by an increase in the relative intensity of the less refrangible lines, and a shift of the maximum of a continuous spectrum towards the red

The general correspondance of these two groups of facts led the authors to seek for an explanation of the spectrum of sun-spots on the hypothesis that the metallic vapours within the spots have a temperature lower than that of the photosphere

Photographs of spot spectra, made with the Snow telescope and a Littrow spectrograph of 18 feet (5 5 m) focal length, and showing a great number of affected lines, were available for the investigation The range of spectrum covered by these photographs is from D to Hδ Supplementary photographs of the spectra of recent large spots, extending from A in the red to the ultra-violet, have been obtained by Mr Ellerman

The laboratory work began with a study of iron and other metals in a synchronous rotating arc, designed and constructed by Prof Crew, but as the necessary photographs involved undesirably long exposures this was not continued It occurred to Mr Gale to try the effect of varying the current strength in an ordinary 110-volt direct-current arc, the difference of potential between the poles being kept approximately constant Photographs were taken, with currents of 30 amperes and 2 amperes, of the spectra of iron, titanium vanadium, chromium, manganese, calcium, and other metals characteristic of sun-spots As the work progressed, a correspondence was noted between the enhanced lines (lines stronger in spark than in arc) and those weakened in sun-spots To get further light on this, photographs were taken of the spectra of the same elements in the discharge of a 600-watt transformer, giving about 6000 volts at the secondary terminals A condenser was used in the discharge circuit, and the potential was increased by an auxiliary air spark in series with the observed spark, both being exposed to a strong blast of air from an electric fan Under these conditions the enhanced lines of the spark are well shown

The instrument used to obtain the majority of the laboratory photographs was a grating spectroscope in the Littrow form of 13 feet (3 96 m) focal length The Michelson grating has 700 lines to the millimetre In taking the comparison photographs of strong- and weak-arc spectra, two of the strong-arc spectra, with varying exposures, were generally placed on each side of the weak-arc spectrum From the four different strong-arc exposures thus obtained that one was selected which was most nearly comparable in general strength with the weak arc spectrum In some cases the spark spectrum was added, adjoining the weak-arc spectrum, with the strong arc spectra arranged as before

Tables are given in the paper which contain the results of a study of the elements titanium, vanadium, iron, chromium, and manganese for the region extending from the ultra-violet to λ 5800 The tables include all the lines which are affected prominently, and which, being strengthened or weakened in spots or in spark or weak arc as compared with strong arc, are of special importance in the investigation

In discussing the behaviour of the lines of the elements mentioned, the investigation is divided into two parts the relation of the weak arc to the strong arc, and of the arc to the spark Two sets of tables are therefore given The first shows the wave lengths of all the lines which are much affected in spots the amount by which they are affected their behaviour in the weak is compared with the strong arc, and in the spark as compared with the weak arc The second set of tables gives a comparison of the intensities of the lines of the same elements which are considerably enhanced in the spark with their intensities in the weak arc The majority of these which occur in the less refrangible part of the spectrum are weakened in spots, and such lines therefore appear in both sets of tables As, however most of the strongly enhanced spark lines occur in the violet and ultra-violet—where the spot lines seem to have the same intensity as the Fraunhoferic lines—independent lists of these lines have been added, since the evidence afforded by them as to the relation of spark to weak arc is extremely important

The authors summarise some of the results accruing from the investigation as follows —

(1) More than 90 per cent of the lines in the tables which are strengthened in sun-spots are found to be strengthened in passing from a 30-ampere arc to a 2-ampere arc

(2) More than 90 per cent of the lines shown by the tables to be weakened in sun-spots are weakened or absent in the 2-ampere arc

(3) More than 90 per cent of all the enhanced lines included in the tables are weakened or absent in the 2-ampere arc

(4) In a list selected at random of 152 lines which are not spot lines no cases were found of lines strengthened in the low-current arc

In discussing the temperature hypothesis as the probable explanation of the observed phenomena, some of the points made are —

(1) Waidner and Burgess's investigation of the temperature of the arc showed that the temperature of the crater was reduced 70° when the current was reduced from 30 to 15 amperes As the relative intensities of the lines undergo no material change in passing from 30 to 15 amperes while the change from 30 to 2 amperes is very pronounced, the temperature of the crater is probably considerably reduced at 2 amperes

(2) Since the enhanced lines of the spark diminish in intensity in the 30-ampere arc, and are still further reduced in the 2-ampere arc, no explanation hitherto advanced to account for these lines appears adequate in the present case, unless it be the explanation based on change of temperature

[1] Abstract of an advance proof from Mount Wilson Solar Observatory of a "Preliminary Paper on the Cause of the Characteristic Phenomena of Sun spot Spectra." (Contributions from the Solar Observatory No. 11) By George E Hale, Walter S Adams and Henry G Gale The paper is to be published in a future number of the *Astrophysical Journal*

(3) The behaviour in stars of the lines affected in sun-spots appears to be consistent with the view that temperature changes alone are sufficient to account for their variation in intensity (In this connection the authors formerly were inclined to the view that the presence of sun-spot lines in the spectra of red stars indicated the presence of many spots like those on the sun Recent work has led them to the opinion that the comparatively low temperature of these stars offers the simplest explanation of the observed phenomena The latter opinion had previously been arrived at and published by Sir Norman Lockyer in a paper "On the Relation between the Spectra of Sun-spots and Stars"[1]) In α Orionis—which from other considerations has been regarded as much cooler than the sun—lines that are strengthened in sun spots are still further increased in intensity, and in Arcturus, which is always assumed to be intermediate in temperature to α Orionis and the sun, the intensities of its lines have been shown by Mr Adams to agree remarkably with those observed in sun-spots

In an addendum to the paper an account is given of further work with (1) the flame of an ordinary arc, (2) a modified form of a Moissan electric furnace

It was found that the spectrum furnished by the flame of the arc—which is undoubtedly of a lower temperature than the core—showed changes of intensity similar to those observed with the 2 ampere arc and synchronous arc Comparison of the lines affected in the flame with those affected in the weak arc showed that, of the lines of Ti V, Cr, Fe, and Mn which were compared, nearly 90 per cent were affected in the same direction, and of these latter the same proportion were affected to a like amount Consequently a large majority of the lines strengthened in sun spots are relatively strengthened in the flame while those weakened in sun-spots are relatively weakened in the flame

The work with the electric furnace was done under conditions which the authors state, eliminated all possible electrical effects, and left temperature as the only possible agent for producing any variations in intensity of the spectrum lines Only Mn and Fe were investigated in this way but the resulting spectra again showed great similarity to the weak-arc spectra the majority of the lines being affected alike in the two cases

At the end of the paper a few objections which can be laid against the temperature hypothesis are touched upon

In a note added on October 2 an observation is included which seems to leave no doubt as to the comparatively low temperature of sun-spots At least one of the titanium flutings which occur in the flame of the arc has been clearly demonstrated to be present in two of the best spot-spectrum photographs

The work is regarded by the collaborators as being only at a preliminary stage but it is evident that it will with subsequent work on similar lines have an important bearing not only on the relative temperatures of sun-spots and photosphere but also on the temperature classification of stars

ANTHROPOLOGICAL NOTES

TO the second number of *Bulletins et Mémoires de la Société d'Anthropologie de Paris* (ser 5, T vii, 1906) Lieut Desplagnes contributes an interesting paper on a little-known region of Central Nigeria, lying at the base of the plateau of Bandiagara (Banjagara), in the Massina district This lake region seems to have been inhabited from the earliest antiquity, and in the Polished Stone period to have supported a dense population at a high grade of civilisation to which numerous Megalithic monuments and a quantity of stone weapons and implements bear testimony, and long before our era examples of metal working, weaving pottery, &c, show the industrial stage to which the inhabitants had attained The character of the remains, physical and cultural, seem to suggest an Eastern origin for these early occupants who were probably related to the ancestors of the Galla-Somali peoples Later on, the nomad and pastoral peoples of the Sahara, attracted by the well watered pastures poured down from the north, and the tribes from the forests pressed up from the south, but all of these, though attaining right by might, had no aptitude for organised industry, and the primitive inhabitants were utilised as a sort of caste of workers, superior to slaves, but yet not mixing with the conquering clans In the smiths, weavers, fishers and potters, are found the descendants of the earlier owners of the land, while others maintained their independence by taking refuge in the islands in the river, the Sorkos, or in the surrounding mountains, the Habbès The paper deals chiefly with the Habbès, describing their traditions customs, habits, dwellings, industries, religious ideas, and sociology, in all of which they differ from their neighbours The illustrations give an idea of the character of the country and the people, and the photographs of the masked figures in the religious dances, supposed to represent the Spirit of the Ancestors, are of particular interest

L'Anthropologie, Tome xvii 1906, contains the first instalment of a study by Dr E. T. Hamy, 'Les Premiers Gaulois' Dr Hamy attempts to trace the physical characters of these invaders of northern Italy in the early Iron age from the evidence of the tumulus burials in France The evidence is unfortunately very scanty, but it is worthy of note that the skulls in the neighbourhood of the forest of Châtillon have a cephalic index ranging from 80 to 84 with an altitudinal index of 88 to 93, although one skull from Banges, in the same district, has an index of 73 1 This is followed by a paper by Mr Ed Piette, "Le Chevêtre et le Semi domestication des animaux aux temps pléistocènes, with many figures showing clear representations of halters in the engravings from the caves of Brassempouy, Mas d'Azil &c This communication forms the ninth in Piette's series of prehistoric ethnographic studies, and his last, for the volume ends with a notice of his death and a recognition of the great services which he has rendered to the science of prehistoric ethnography The second part of "Les Restes humaines Quaternaires dans l'Europe Centrale" by Mr H Obermaier, continues the useful summary of the evidence for Quaternary man in Europe The cautious tone of the writer is seen in the brevity of the list of human remains 'sûrement quaternaires' when compared with the list of, "Indications à écarter comme erronées douteuses ou insuffisantes"

In *Globus*, lxxxix, Nos 14 and 15, Mr Vojtěch Frič gives an account of his travels along the Pilcomayo—a tributary of La Plata—in Central Chaco with notes on the Pilagá and other Indians and illustrations showing the character of the country and the fine looking type of inhabitants Among the majority of these tribes it may be noted, the women propose marriage to the men the *modus operandi* differing among the different groups The method employed by the Pilagá women is to place a certain zigzag mark on a certain tree the chosen man presents himself, and no further ceremony is needed No 17 contains a description, by Dr Claus Schilling, of the Tamberma, who until a few years ago were an undiscovered people near the borders of Togo The illustrations taken by the author show the peculiar architecture and costumes of the district This paper is followed by a short account of another African people, the Mpororo of the north-west corner of German East Africa, by Oberleutnant Weiss Nos 18 and 19 of the same periodical contain articles on the Gold Coast negroes by the medical missionary Dr H Vortisch, who gives a review (with illustrations) of their physical features clothing character, family life, sociology political organisation, &c, and a careful record of their musical instruments, thirteen of which are figured Mr Erland Nordenskjold contributes an article to *Globus*, lxxxix, No 22, "Der Doppeladler als Ornament auf Aymarageweben," tracing the degeneration of the zoomorphic design through varying stages In a series of papers (in Nos 11, 20, 24, and xc, 1) Dr Theodor Koch Grünberg describes his travels "Kreuz und Quer durch Nordwestbrasilien," giving excellent pictures of the scenery and of the natives, with a map to show the linguistic grouping Of particular interest are the native drawings of animals In xc No 4, W von Bülow criticises the theories of Percy Smith, F Tregears,

and A. Krämer, on the origin of the Polynesians, and identifies Savaiki (Havaiki, Avaiki, Savaii, &c.) with Java, *i.e.* *sawah* (Javanese) = rice-field, and *iki* (also Javanese) diminutive suffix.

GEOLOGICAL RESEARCH IN SOUTH AFRICA.[1]

THE last number of the Transactions of the Geological Society of South Africa cannot fail to attract a greater number of geologists to follow the rapid progress being made in South African geology. This journal once threatened to be the dreariest; it is rapidly becoming one of the most interesting.

The visit of the British Association to South Africa has no doubt directed attention to the many points of interest in the geological history of one of the oldest land masses in the world.

Recent work between the Cape and the Zambezi has shown that the South African rocks present phenomena unparalleled elsewhere. The Dwyka Conglomerate undoubtedly affords the finest study of an ancient Glacial

This is a very well preserved striated surface of flagstone forming one of a series of such exposures at Blaauwbosch Drift. The striæ run from N.E. to S.W. The grey patches on the glaciated rock, which are only faintly shown in the photograph, are delicate Bushman chippings. The upper rock seen at the top right-hand corner is boulder shale. From "Transactions of the Geological Society of South Africa."

period. With this geologists have become familiar, but no more convincing examples have been found than those of the glaciated surfaces and boulder beds in Griqualand West described and beautifully illustrated by Messrs. Young and Johnson, but the Dwyka is not the oldest glaciation. Evidences of another have been obtained by Mr. Rogers from the Table Mountain Sandstone series, and he now describes a third and much older glaciation towards the summit of the Griquatown series. South Africa is thus yielding information on those points on which the older formations of the northern hemisphere are generally so persistently silent.

The unfossiliferous and lithologically similar pre-Cape rocks have of late years been proved to be built up of several unconformable groups. The number is added to in the present volume. They also contain rocks of a unique character, none more so than the remarkable Blink Klip breccia of the Griquatown series described by Mr. Rogers. This is a brecciated rock, exceeding 200 feet in thickness, formed by the collapse of the Lower Griquatown series into hollows dissolved out in the underlying limestones and dolomites.

That the interesting character of South African geology is not recognised to the full extent it demands is perhaps due to the overwhelming preference hitherto given to the economic study of the gold-bearing conglomerates and coal deposits. A utilitarian spirit still apparently holds a prominent place among several members of the Johannesburg school of geologists, of which an indication will be found in the present volume. Why, it is asked, is the Transvaal Survey engaged in the investigation of "outside" areas, where "outside" seems to include everything beyond the immediate vicinity of the golden city? Considering the number of ridiculously divergent opinions concerning the age, order of sequence and stratigraphical relationship of the gold-bearing conglomerates, it is evident that either the problem lies beyond solution or that the secret will be found in the outlying districts. That the enveloping movement around the Central Rand is being rapidly and systematically carried on is shown by the work of the Transvaal surveyors and by that of Mr. Rogers in Griqualand West. The results obtained by both surveys not only justify their existence, but warrant that in happier times, they will receive a more liberal help. The fuller knowledge so obtained can afterwards be applied to any special economic region with that nicety of attention to detail on which the success of applied geology so much depends.

W. G.

THE SCOPE AND PROBLEMS OF PROTOZOOLOGY.[1]

PROTOZOOLOGY, a science that has only in most recent times attracted general attention, is nothing more or less than the study of a group of organisms which zoologists term protozoa, and therefore, in order to make clear the meaning and scope of the science, it is only necessary to explain, first, what the protozoa are, and secondly, why one should study them—to the extent, that is to say, of having independent university chairs for that purpose.

In sea-water or in the waters of lakes, rivers, ponds and ditches, in any small puddle or in damp earth and moss, in fact, in any situation where sufficient moisture exists to float their tiny bodies, protozoa can almost always be found, usually in abundance. If an infusion or liquid containing organic matter be exposed for a sufficient time to the air, protozoa will make their appearance in it and multiply. And, finally, there remains to mention a large but very important section of the protozoa which do not get their living in an honest and independent manner, but live as parasites of other animals and nourish themselves on the internal juices of their hosts; it may be in the digestive tract, or it may be in the blood, or in some other organ or tissue of the body. Thus the situations in which protozoa may be found show the utmost diversity of character. It must not be supposed, however, that every minute living thing which can be detected growing or moving in a moist environment is necessarily one of the protozoa. Here we have to draw some distinctions and to eliminate certain types of organisms. In the first place, the protozoa must on no account be confused with the bacteria, a group of organisms which stands sharply apart from other microscopic forms of life. Apart from the bacteria, the world of microscopic life can be further divided into two groups, the one comprising those of animal nature and habit, the other those more distinctly vegetable in their mode of life. The distinction between plant and animal, when applied to these lowly forms of life is, however, a most unnatural and artificial line of cleavage. It is impossible, therefore, to use vegetable or animal characteristics as a criterion for separating these minute organisms into natural groups. For this reason it has been proposed to unite all these primitive forms of life into one group

[1] Abridged from the inaugural lecture delivered before the University of London on November 1, by Prof. F. A. Minchin, Professor of Protozoology.

under the name protista, meaning literally the very first things, living things (zoa) being understood The protista would then rank as a separate *kingdom*, that is to say, as a category equivalent to the animal and vegetable kingdoms respectively

Theoretically, there can be no doubt that to group all these primitive living things together as protista is the most natural and proper way of dealing with them We should then talk of protistology rather than protozoology, and of a protist rather than of a protozoon which would at least be more euphonious But this method of dealing with these creatures is inconvenient and unsuitable in practice, chiefly because the group protista comprises such a vast array of organisms of different types that no one investigator can deal with them all satisfactorily, or with the different technical methods requisite for their study, and a division of labour has become necessary Hence the bacteria have been assigned to the domain of a special science, bacteriology the botanists claim for their sphere of investigations all those protista which are of vegetable nature, and there remain, finally, for the zoologist, those protista which can be regarded as *animals*, and which are therefore, termed the *protozoa*

We have now got so far, that the protozoa are minute, microscopic forms of animal life There are, however, many minute animalcules which are by no means to be considered as protozoa If we compare the protista with higher animals and plants, we find at once a fundamental difference In the body of a protist the living substance, the protoplasm, is not divided up into cells, but forms one simple mass, that is to say, the whole body of a protist is comparable to a single one of the cells that build up, in vast numbers, the complex body of a higher animal or plant Expressed briefly in the technical jargon, we may say that a protist is a unicellular organism, and that a protozoon is a protist of animal nature Since such organisms may be regarded as the most primitive types of animal life, the earliest, probably, to appear upon our globe, they have been named the protozoa, or "first animals"

We are now in a position to attack the second question that was suggested for consideration, namely, what is the interest and importance specially attaching to the study of the protozoa? This is a matter which can be considered most conveniently from two different points of view, the theoretical and the practical In dividing my discourse into these two heads, however I do not wish to be understood to imply that there is any real distinction between theoretical and practical science The whole history of human progress and culture shows that what is theoretical to-day is practical to-morrow This is such a commonplace that it would be superfluous to waste time by citing instances The theoretical knowledge of scientific principles must necessarily precede their application, hence to discover these principles is, even from the practical point of view, the most important occupation of the human intellect This is a point of view which cannot be too strongly emphasised, and to which I shall return again

From the theoretical point of view the protozoa are of the greatest interest on account of their primitive nature, and the light which they consequently throw on many obscure vital processes The cells which compose the tissues of higher animals have become extremely specialised for their particular functions and modes of life, and their structural or developmental characters tend to follow certain stereotyped patterns and to conform to uniform rules of procedure, due perhaps to a common origin and ancestry In the protozoa on the other hand each individual is an unspecialised cell, capable of performing equally well all the functions of life as a free and independent living organism, and the structural features or developmental processes of protozoa exhibit the utmost possible diversity of character Only by the detailed comparative study of this primitive diversity is it possible to discover the course of evolution which has culminated in the relatively uniform characters of cell-structure and cell-behaviour in the higher forms, and so to elucidate the true significance of many obscure cytological problems Just as the higher division of the animal kingdom may be reasonably supposed to have originated from protozoan ancestors, so the cytology of the higher animals may be said to have its roots in the cytology of the protozoa, and the same is perhaps true also of other subdivisions of biological science.

Turning now to the practical aspects and applications of protozoology, we find that these arise from the peculiarity already mentioned of many of these organisms, namely, that they live as parasites of other animals, and may produce diseases in them For this reason the investigation of the protozoa has, like that of the bacteria, become of immense importance to medical and veterinary science, and for this reason protozoology has taken shape as a definite science, and has gained recognition, outside zoological circles, just as bacteriology did before it Formerly it was always bacteria that were sought for as the agents of diseases Now it is known that many diseases are caused by protozoa, and not by bacteria, and it is suspected that this is the case also in certain diseases of which the cause is still obscure

Although, as I have stated, the practical importance of the study of protozoa has only been recognised generally in the last few years, nevertheless the actual discoveries of important disease-producing protozoan parasites date back, in some cases a quarter of a century Prof Koch of Berlin, has directed attention to three great discoveries, each of which opened up the way for a new line of investigation, and was of the utmost importance in establishing the true cause of diseases previously mysterious in nature The first was the discovery of the malarial parasites by Laveran in 1880 The second was the discovery of the parasites of the so-called Texas fever of cattle in America by Smith and Kilborne in 1893 The third was the discovery of the parasites of tsetse-fly disease in Africa by Bruce in 1895

The malarial parasite was first observed by Laveran then an army surgeon, in the blood of fever patients in the military hospital at Constantine in Algiers Though working with inferior microscopical apparatus, Laveran described clearly all the principal stages that can be made out in human blood This sensational discovery was received everywhere with coolness and disbelief At that time the cause of malaria was generally believed to be a bacterium, which was named *Bacillus malariae*, and it was some years before the bacillus was discredited, and Laveran's parasite established, as the true cause of the disease It still remained a mystery, however, in what way this minute organism got into the human blood, and the view was put forward that it gave rise to minute germs which passed out of the body and were scattered abroad, and which, like many other germs of protozoa, were able to float in the air It was supposed that those germs were then inhaled by healthy persons, and so gave rise to the disease This was simply an extension of the old miasma theory, the notion that the disease was contracted by inhaling the air of swamps and marshes, a notion expressed in the word malaria, meaning literally bad air It remained for a countryman of ours, Major Ronald Ross, to discover, by a series of brilliant experiments and observations, the part played by mosquitoes in disseminating the disease It was found, however, that a remarkable relation existed between the species of mosquitoes and the species of malarial parasites The common gnats, for instance, belonging to the genus Culex, are incapable of transmitting the malarial parasites of man but convey those of birds from one bird to another The mosquitoes which carry the malarial parasites of man belong to a different genus, Anopheles, and they in their turn are incapable of transmitting the malarial parasites of birds This is one of those remarkable adaptive specialisations so often seen in nature

Let us now follow the course of infection briefly If a mosquito bite a man suffering from malaria, it takes in a drop of blood in which are contained various stages of the malarial parasite The blood is, of course, digested slowly in the mosquito's stomach, and if the mosquito be a Culex all stages of the parasite are digested also but if the mosquito be an Anopheles, certain stages of the parasite resist digestion In the parasite of pernicious or tropical malaria, the resistent stages have a form like a sausage, and are known commonly as crescents These crescents undergo changes in the mosquito's stomach which give rise to sexual forms, minute, slender males, and relatively large, bulky females Fertilisation takes place

and the result is a slender, worm-like creature which progresses by gliding movements, and which penetrates into the wall of the mosquito's stomach, and there multiplies to form an immense number of very minute germs, producing a small tumour on the outer side of the wall of the stomach After a time this tumour bursts, and the little germs pass into the blood of the mosquito They are carried to and fro in the mosquito's blood circulation, but ultimately pass into its salivary glands, and the mosquito is now infectious When it next feeds, a swarm of the malarial germs passes down its proboscis into the puncture it makes, and in this way the disease is passed on from one person to another

The second important discovery mentioned above, that of Smith and Kilborne, concerns a fatal epidemic disease of cattle and other animals, sometimes termed red-water In this case the two American investigators discovered, not only the cause of the disease, but the method of transmission The parasites are tiny, pear-shaped bodies which penetrate the blood corpuscles and multiply there, so that two or more parasites may be found in one corpuscle Similar parasites are now known to occur in sheep, horses, dogs, monkeys, and rats, but are not known with certainty to occur in human beings

Smith and Kilborne discovered that the parasites of cattle red-water were transmitted by ticks, but not quite in the same way as malaria is transmitted by the mosquito When a tick feeds on an infected animal, it does not itself become infectious, but gives rise to offspring which are capable of infecting healthy animals, so that the parasite passes through two generations of ticks Unfortunately, nothing intelligible is known of the development of the parasite within the tick, and an important field of investigation is as yet untrodden

[For an account of the third discovery referred to above, that of Bruce, see NATURE, November 15 (p 56)]

Enough has been said, I think, to show that protozoology offers a most interesting and important field of investigation, of which as yet only the fringe has been touched Almost every day brings news of some new discovery in this field There are still, however, many questions to be answered relating both to protozoa and to the diseases caused by them, especially in the tropics, where insect life of all kinds is so developed, and there are so many different blood-sucking insects to carry infections of all kinds

This brings me now to the concluding section of my discourse—what are the problems of protozoology and how should they be attacked? The problems that present themselves to the student of the protozoa are principally of two kinds In the first place, there are purely zoological problems, such as the recognition, classification, and registration of the innumerable varieties and forms of these tiny creatures, the tracing out of their complicated life-histories and their bewildering changes of form and appearance during development, and the study of their vital processes and reactions to surroundings, as throwing light on many problems of cytology, heredity and evolution, of psychology and physiology In the second place, the results obtained by the zoologist—that is to say, by anyone working according to zoological methods—must be applied to the elucidation of questions relating to disease in man and beast, in other words, to the requirements of the healing art, as practised by the medical man and the veterinary surgeon Here, however, all the zoologist can do is to supply a knowledge of facts and principles of which the healer can make use, and the final beneficial result must be obtained by a collaboration of the investigator and the practitioner

Although it may be urged with justice that the most important outcome of human science is its application to human needs, it would be the greatest possible mistake to attempt to confine any scientific study to just those problems which are thought likely to yield results of direct practical importance Such a course would be short-sighted in the extreme, and would tend to produce a narrow outlook and a limited range of ideas, in the place of broad fundamental principles on which to base deductions for practical guidance Thus, to apply this statement to the special case of protozoology, the forms most important for medicine are those which are parasitic upon man, but it would be absurd to study only these forms, first, for practical reasons, because it is easier to experiment upon animals than upon our fellow-men, and, secondly, because the study of many different parasites and their development supplies analogies which throw light upon obscure points in the life-history of those attacking man But if we take a still wider view, we find that three-fourths at least of the protozoa are not parasites at all, but live free, independent lives in various situations

It is obvious, therefore, that to understand properly the highly-specialised parasitic protozoa we must be acquainted with the more primitive free-living forms first and foremost This conclusion may be illustrated by a few facts from the career of the late Dr Fritz Schaudinn, whose recent death at the early age of thirty-five was a most deplorable event, cutting off an investigator who, by his genius and industry, had won the very foremost place in the ranks of protozoologists The bulk of his work was done on forms not of importance from the practical that is to say, the medical, point of view, and yet it is not too much to say that his work has modified all our ideas upon the protozoa and has built up the modern conceptions of these creatures, so that no one at the present time can write upon them without taking into consideration the facts and principles discovered by Schaudinn, whose work is a living demonstration of the practical, as well as theoretical, imporance of non-practical scientific study

The physician and the zoologist work from points of view which, though apparently opposed, are in reality mutually helpful The physician, of course, takes the side of the patient, and his only object is to extirpate the parasite The zoologist, on the other hand, identifies himself as an investigator with the interests of the parasite and tries to become acquainted with all its migrations and changes, studying it for its own sake In short, the zoologist must deal with protozoa as if he loved them, but the medical man as if he hated them There can be no such thing as protozoology studied exclusively in relation to medicine Protozoology must be studied as a science in which all knowledge is helpful, directly or indirectly When the protozoologist has worked out his life-histories and obtained his results, then the medical man steps in and carries off the honey to the medical hive In this way by the cooperation of the purely scientific investigator with the practitioner, we may hope that protozoology may have before it a bright future, in which both theoretical science and the practice of the healing art may be advanced and benefited to an equal degree

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —The Vice-Chancellor announces that the treasurer of the Cambridge University Association has recently paid to the benefaction fund of the University the sum of 904*l*, resulting from the appeal for the building fund for the new museum of archæology and ethnology This payment, together with 60*l* already received by the benefaction fund, is intended to form a nucleus of 1000*l* for the building fund of the museum The Vice-Chancellor publishes also a list of subscriptions, paid or promised amounting altogether to 12,325*l*, toward the building fund of the department of agriculture

After considering a resolution of the Classical Association in favour of abolishing the Greek grammar paper in the previous examination, the board of examinations proposes that in part i of the previous examination (*a*) the separate paper at present set on Greek and Latin grammar be discontinued, (*b*) the time allowed for the two papers on the Greek and Latin classics be increased from 2½ hours to 3 hours, in order that more questions in grammar may be set than at present, the questions in grammar to be such as arise from or are suggested by the passages given for translation, (*c*) the papers set on the alternatives to the Greek and Latin classics be similarly lengthened with the same object, and (*d*) these changes shall first take effect at the examination to be held in October, 1907

Sir James Dewar, who will be unable to lecture next term, has nominated Mr H O Jones, of Clare College as deputy for the Jacksonian professor of experimental philosophy during the Lent term of 1907 Mr Jones has

been re-appointed demonstrator to the Jacksonian professor until September 30, 1911

The Cavendish professor of experimental physics and the Lucasian professor of mathematics have elected Mr F Horton fellow of St John's College, to be Clerk Maxwell student in succession to Mr O W Richardson, of Trinity College who has resigned the scholarship

---

THE treasurer of Guy's Hospital has received two anonymous donations of 200*l* and 10*l* respectively toward the fund for the endowment of medical education and research at Guy's Hospital

As part of the scheme of university courses in advanced zoology Dr W G Ridewood will deliver two lectures on "The Structure and Affinities of Cephalodiscus" in the zoological lecture room of University College Gower Street W C, at 5 p m on December 5 and 12 Admission to the lectures is free by ticket obtainable on application to the Academic Registrar University of London

IT has been suggested to provide a regularly equipped central station for lighting the buildings of the University of Sydney The work in this station might, it is thought, form part of the college engineering course In addition to work connected with the generation of power, the scheme would provide opportunity for testing for faults in mains, and for training in the commercial side of station work

THE Senate of the University of London has received from the Clerk of the Privy Council an intimation that the King in Council has approved the new statutes made for the management of University College and for the constitution and management of the North London or University College Hospital and the School of Advanced Medical Studies connected therewith All the arrangements made in connection with the incorporation of University College in the University will come into operation on January 1, 1907

THE University of California has been presented with the herbarium and botanical library of Mr and Mrs T S Brandegee of San Diego The herbarium *Science* states is one of the most important in the west of the United States since it contains something more than 100 000 sheets of carefully selected plants, mostly representative of the Mexican flora, which for many years has been Mr Brandegee's chosen field and of the flora of California and neighbouring States, which has received careful treatment at the hands of Mrs Brandegee We learn from the same source that the Academy of Natural Sciences of Philadelphia has acquired two important zoological collections One of these is the Gulick collection of Hawaiian land shells, which served as the basis of Rev John T Gulick's well known work "Evolution Racial and Habitudinal" and the other is the Tristram collection of birds numbering some 7000 skins and representing upwards of 3000 species This is the second collection made by the late Canon Tristram, the first one having been secured some years ago by the Liverpool Museum

THOUGH it was more common a few years ago there is still a disposition in some educational circles to refer to the study of the applied sciences as merely "bread-and-butter studies" In a recent address to the Wolverhampton Technical Schools published in pamphlet form by Messrs Longmans, Green and Co Prof Ripper has much of value and interest to say as to this contention He urges very rightly that these studies if properly pursued must develop scientific methods of thought and give new and higher interests to the student As Prof Ripper said "The same spirit which originally led to the study of technical science will tend also to the desire to travel beyond it The same qualities which have made the technical expert will tend also to make the enlightened and cultured citizen" The address concludes with an optimistic estimate of the educational outlook There is, Prof Ripper thinks, much more demand than formerly for technically trained assistants Employers are offering facilities for extended courses of study for their apprentices, for example several firms in Sheffield arrange for some of their apprentices six months' study at the university and six months' study in the works Employers, too, are immensely stimulating the work of education by making their appointments and promotions depend in an increasing degree upon educational fitness.

THE anniversary address of the Royal Scottish Geographical Society was delivered by Sir George Goldie, president of the Royal Geographical Society, on November 22 The subject of the address was "Geographical Ideals" Among a variety of subjects discussed in the address, great prominence was given to the question of the value of geography in war This value, Sir George Goldie said, might be best brought home to our own countrymen by recalling the enormous expenditure in which the want both of maps and of geographical training of our officers indirectly involved us during the Boer war He went on to say that he could speak confidently on these points from having served for nearly a year on the Royal Commission on the South African War He added that the lesson of the war in this respect has not been altogether forgotten During the last four years a certain amount of money has been expended in Imperial mapping of hitherto unsurveyed regions, and if this process is not altogether arrested by a spirit of false economy, we may possibly at some distant date possess fairly adequate maps of all British possessions Our ideal must be to reach the level attained by Japanese and German officers Sir George Goldie finally dwelt upon the importance of educating the people on the subject of geography and its removal from the subjects of the examinations for the Foreign Office and Diplomatic Service

THE report of the work of the department of technology of the City and Guilds of London Institute for the session 1905–6 is now available Statistics are given showing the continuous growth of the work of the department since 1879 The number of subjects in which examinations were held during the session under review was the same as in the preceding year but the number of separate classes increased from 2601 to 2820, the largest number recorded There was, too a marked increase in the number of students in attendance the number having risen from 41 618 to 44 464 At the examinations at the end of the session 20 610 candidates were presented in subjects of technology and of these 11 665 passed Numerous candidates were examined in India and the colonies We notice that Cape Colony Jamaica, Malta, Suez, Melbourne Granville (New South Wales) all presented candidates, but that the largest contingent of colonial candidates was that sent by New Zealand The system of inspection inaugurated by the institute grows in usefulness The inspectors appointed by the institute are men and women possessing somewhat different qualifications from those of the inspectors of the Board of Education and their work is supplementary to that of the Board Whilst the Board's inspectors report upon the general equipment of technical schools and upon the general character of the teaching those of the institute are concerned only with the special facilities provided for trade instruction, and report on the methods and the value of the teaching as part of the training of artisans

Chemical Society, November 15 —Prof R Meldola, F R S president, in the chair —The determination of the rate of chemical change by measurement of gases evolved Preliminary notice J L F **Lamplough**. When a chemical reaction takes place in solution resulting in the formation of a gaseous substance, the solvent becomes supersaturated with the gas The excess of gas so dissolved may be almost entirely expelled by brisk agitation Under conditions of efficient stirring the rate of evolution of a gas furnishes an accurate and trustworthy method of investigating reactions —The formation and reactions of imino-compounds, part ii, condensation of benzyl cyanide leading to the formation of 1 3-diaminonaphthalene and its derivatives E F J **Atkinson** and J F **Thorpe**.—Note on the anhydride of phenylsuccinic acid F B **Dehn** and J F **Thorpe**. The authors conclude that the anhydride of phenylsuccinic acid exists only in one form, which melts at 53°–54° —Influence of sodium arsenate on the fermentation of glucose by yeast-juice Preliminary notice A **Harden** and W J **Young**. It has been previously shown

that the addition of a soluble phosphate to yeast-juice containing glucose increases the rate of fermentation, which proceeds until an extra amount of carbon dioxide (equivalent, molecule for molecule, to the phosphate added) has been evolved The phosphate at the same time undergoes a change which renders it non-precipitable by magnesia mixture When an equivalent amount of arsenate is substituted for the phosphate a similar acceleration is produced, but the rate is greatly increased, and continues for a time without change until many times the equivalent of carbon dioxide has been evolved, and then falls gradually —Xanthoxalanil and its analogues S **Ruhemann.**—Derivatives of cyanodihydrocarvone and cyanocarvomenthone A **Lapworth.**—Reactions involving the addition of hydrogen cyanide to carbon compounds part vi the action of potassium cyanide on pulegone R W. L **Clarke** and A **Lapworth** —The influence of various substituents on the optical activity of tartramide, part ii, P F **Frankland** and D F **Twiss** The authors have prepared and described the n and iso *propylamides*, the *allylamide*, the n- and iso *butylamides*, and the n-*heptylamide* of tartaric acid —The influence of various substituents on the optical activity of malamide P F **Frankland** and F **Done** The authors described the preparation and properties of the *methylamide ethylamide*, and iso*propylamide allylamide* and iso*butylamide* n-*heptylamide piperidide* and *phenylhydrazide* of ordinary *l* malic acid

Royal Meteorological Society, November 21 —The abnormal weather of the past summer and some of its effects W **Marriott.** The principal features of the weather over the greater part of England—especially the south-east—were the high state of the barometer throughout the whole of the period except a portion of August, the high temperature in July August, and September, the great amount of sunshine and the deficiency of rainfall Over the south-eastern portion of England more than 900 hours of bright sunshine were recorded during the four months June to September while at a few stations in the extreme south and on the east coast more than 1000 hours were recorded The sunshine was more than 200 hours above the average over the Thames basin and on the coasts of Lancashire and North Wales The most remarkable feature of the weather during the past summer was the exceptional heat wave which occurred between August 30 and September 3 The temperature rose above 90° over a large part of England on four consecutive days viz August 31 to September 3 With the advent of the hot weather the death-rate increased considerably and it was pointed out that when the mean maximum temperature for the week reached 72° the death-rate at once began to rise The increase of the death rate was made up almost entirely of infants under one year of age This was shown to be due to the prevalence of infantile epidemic diarrhœa which sets in when the mean maximum temperature for the week rises above 72° —The International Congress on Polar Exploration held at Brussels in September Dr H R **Mill**

Mineralogical Society November 13 —Prof H A Miers F R S, president, in the chair —Growth of crystals of soluble salts on each other T V **Barker** This paper is a continuation of the author's previous work on the growths of salts on isostructural minerals to those of soluble isomorphous salts on each other The group now investigated is that of the chlorides bromides, iodides and cyanides of Na, K, Rb, Cs, and Am which crystallise in the cubic system The view previously entertained that parallel growths are conditioned by a similarity of molecular volume is again found to hold good, some apparent exceptions are explained by the presence of isodimorphism One pair of salts however NaCl–KI, yield parallel growths although the molecular volumes are greatly different, this is perhaps to be accounted for by the fact that the molecular volumes are almost exactly in the ratio 1 2 —Notes on some Bolivian minerals I J **Spencer** Descriptions are given of crystallised jamesonite semseyite from Oruro, new crystal forms on andorite, chalcostibite from Oruro, augelite from Oruro sylvanite from Tatasi and Tasna, tetrahedrite from Huanchaca, regular grouping of stannite and tetrahedrite, valentinite, cassiterite, tourmaline and tourmaline-hornfels fluor, apatite, cupriferous miargyrite from Tatasi, crystallised miargyrite from Aullagas, jarosite from Chocaya chalybite from Chorolque and Tatasi, enargite from Chorolque —Note on ilmenite from Brazil G F Herbert **Smith** The crystals have three habits *cam camrX cuXrs*, differing slightly from those described from the same locality by Hussak The hemihedrism is shown by striations on the prism faces, some magnesium is present —Description of the Lengenbach Quarry and of the minerals found there in 1906 R H **Solly** The now well known quarry was opened about the year 1850 and various new minerals were described by Des Cloizeaux and others From 1860–70 a level was driven in a direction at right angles to the stream and in it were found the specimens described by Vom Rath In the decade 1890–1900 a little work was done each summer resulting in the specimens studied by Baumhauer Since 1900 Francis Jentsch and his partners have worked the quarry regularly each summer In 1902 they came across the old tunnel constructed in 1731 the existence of which had been quite forgotten Up to 1898 eighteen mineral species had been found, of which four are peculiar to the quarry since that date twenty-five additional species of which no fewer than twenty are new to science have come to light Nine of the new species have been named two are pseudomorphs and nine owing to paucity of material, have not yet been described The minerals found this year include trechmannite (fine crystals) baumhauerite (curiously striated and distorted crystals) seligmannite (a large crystal 20 mm in length) jordanite (a twin about 101) dufrenoysite (a twin about 001) pseudomorphs of dolomite and baumhauerite after scapolite (?) Note on the thirty-two classes of symmetry H **Hilton** Note on a Canadian mineral Prof **Harrington** Specimens of turnerite from Cornwall were exhibited by Mr **Russell**, and crystals of sartorite by Dr **Trechmann**

DUBLIN

Royal Irish Academy November 12 —Prof F A Tarleton president in the chair —The stability or instability of the steady motions of a perfect liquid and of a viscous liquid part 1 a perfect liquid Prof W McF **Orr** It is known experimentally that when water flows through a circular pipe the steady motion is unstable if the velocity exceed a limit depending on the radius of the pipe Lord Rayleigh has proved mathematically that in this case as well as in others of flow in plane sheets including that of a liquid which is shearing uniformly the fundamental modes of "free disturbance" are stable when viscosity is ignored in the disturbed motion the free periods being real There is thus an apparent contradiction between theory and experiment It is however contrary to the teaching of Fourier analysis to infer that a general disturbance is stable from the fact that the "free disturbances" possess stability, even of an exponential type In a system disturbed from equilibrium the question of stability is in reality decided by an energy criterion which is as a rule inapplicable to questions of the stability of motion If a liquid bounded by the infinite planes $y=0$, $y=b$ and shearing uniformly in the direction of x is subjected to an initial disturbance for which the stream function is $\psi=\sin lx \sin my$ it appears that, if mb and m/l are each large the disturbance, as shown by equations in which only terms of the first order of small quantities are retained increases in a great ratio as a certain time approaches after which it diminishes indefinitely A similar result is obtained for a symmetrical disturbance of simple type in a circular pipe when the steady motion is that of a viscous liquid When the steady motion is that of a viscous liquid between concentric cylinders one or both of which is rotating a similar result also holds for a two-dimensional disturbance (except the liquid rotates as a rigid body) It is held that these results afford an explanation of the observed instabilities as satisfactory as can be expected from an investigation which ignores viscosity A theorem on moving distributions of electricity Prof A W **Conway** The integrals which express the electric and magnetic forces for a moving distribution in terms of retarded potentials are discussed and it is proved that they obey Maxwell's equations outside the electrical matter, but that

inside the equations have to be modified by adding the convection current to the displacement current, as done by Fitzgerald.—The contact-phenomena at the junction of Lias and Dolerite at Portrush: Prof. G. A. J. **Cole**. The paper describes the microscopic characters of the rocks at and near the junction of Dolerite (or basalt) and calcareous Lias shale at Portrush—a junction of considerable interest in the history of geological opinion. The silicification of the shale is accompanied by the production of abundant minute crystals of a pale green pyroxene. The "bronzite" of Portlock and Oldham, named by them with some hesitation, proves to be a brown mica, locally developed after the formation of the pyroxene. The author has had the advantage of using the original specimens collected by Portlock's survey. Some details as to the later sheets and veins of dolerite are given, and the occurrence in them of differentiation, by gravitation of ferromagnesian minerals to their under surfaces, is compared with similar cases elsewhere.

VIVISECTION

Experiments on Animals By Stephen Paget Third and revised edition Pp xii+387 (London J. Nisbet and Co., Ltd, 1906)

THE new edition of Mr Paget's well-known book appears in time for the inquiry now being made by a Royal Commission on the subject of vivisection It is now exactly thirty years since the first Royal Commission on the subject of experiments on animals made its report A glance at this report is, to us of this generation, a revelation of the enormous progress that has been made in medical sciences during the last thirty years In the report the attention of the commissioners as well as of the witnesses, was almost entirely taken up with the question of physiological experimentation The leading men of the medical profession testified to the dependence of advance in medicine on advances in our knowledge of the workings of the body in a state of health, a proposition which must seem to every scientific man self-evident For the conversion to this view of the ordinary man, who does not think scientifically, the examples adduced by these witnesses must seem to us at the present time very scanty Again and again we have brought up in evidence the discovery of the circulation of the blood by Harvey and of the functions of the anterior and posterior roots by Bell and Majendie, and certain experiments on the growth of bone and on the absorption of ligatures in regard to their surgical application

Although the experiments of Villemin and Chauveau on tubercle are mentioned, the tubercle bacillus was as yet undiscovered Lister had already, for nearly twenty years, been endeavouring to discover the best method of prevention of wound infection, and had introduced antiseptics into surgery, but the antiseptic method had not yet been generally accepted Pasteur was still carrying out his researches on the nature of wound infection, but in 1878, three years after the Commission was appointed, his views had not yet received general acceptance Mr Paget gives a graphic description of a memorable discussion which occurred in this year at the French Academy of Medicine on the subject of puerperal fever In the middle of a long discourse by a doctor on the causes of this mysterious visitation, Pasteur interrupted with the statement that the epidemic was due entirely to microbes conveyed by the doctor and his assistants, and jumping up and going to the blackboard he drew the streptococcus on it, saying, "Tenez, voici sa figure." Bacteriology, in fact, was just being born, and few in this country had recognised the marvellous part it was to play in modifying the relations of man to his environment

From the development of bacteriology during these few years has grown the antiseptic and aseptic treatment of wounds, which is responsible for the saving annually of hundreds of thousands of lives, and for the practical abolition of pain from the surgical wards

The discovery of the tubercle bacillus by Koch has enabled us to deal successfully with numerous cases of tuberculosis in its manifold forms, "we have no longer to reckon with a nameless something, but with a definite parasite whose conditions of life are for the most part already known, and can be further studied" In this way we are in a position, in many cases, to shut off the sources of infection, and so to attain the prevention of this most fatal of all disorders

Since this time one disorder after another has been studied, and has given up its secrets to the bacteriologists The diphtheria bacillus was discovered in 1875, and isolated by Loeffler in 1884 In 1890 Behring and Kitasato discovered the antitoxin which is used throughout the whole civilised world, and has reduced the case mortality by one half

The tetanus bacillus was discovered in 1880, and the tetanus antitoxin by means of which we can protect against the disease though rarely succeed in its cure, in 1894 The horrible disease of hydrophobia was brought under our control by Pasteur in 1885 The cholera bacillus was discovered by Koch in 1883, and the method of preventive inoculation against this disease by Haffkine in 1893

The plague bacillus was discovered in 1894 Since this time, knowing the cause of the disease, it has been possible to track out its whole natural history, and the report of the last Commission on the subject has placed in the hands of the sanitary officials all the facts which are necessary for successfully coping with the disease

The typhoid bacillus was discovered in 1881 An emulsion of this bacillus is now constantly used in Widal's reaction, to diagnose typhoid and to distinguish it from other cases of continued fever Successful inoculations against the disease have been carried out by Wright

The discovery of the bacillus of Malta fever, or Mediterranean fever, by Bruce, has enabled medical men to determine the sources of infection of this disorder, and the resulting measures have this year caused a diminution of the cases from 258 in July, August, and September 1905, to fifteen during the corresponding months of this year,

The microorganisms of malaria and of yellow fever have been discovered and their life-histories worked out The part played by mosquitoes and gnats in the propagation of these diseases once having been recognised, it has been possible to wage a successful war against both these disorders Where preventive measures have been thoroughly carried out, these diseases, which previously decimated the population, have been practically stamped out I may mention here simply the case of Ismailia (malaria), Havana (yellow fever), and the Panama Canal (yellow fever) All these results, involving probably the saving of hundreds of thousands of lives yearly, have been accomplished by a science which has hardly attained its majority, and which is the direct outcome of the application of the scientific method for which a strong testimony was borne before the Royal Commission of 1875

These examples, though representing the results which can be most easily appreciated by the unlettered and unscientific, make up only a fraction of the benefits that have accrued to man as the result of the continuation of experiments on animals. The control of the bodily functions must be founded on a knowledge of those functions. Medicine must repose on physiology, or be reduced to charlatanism and empiricism.

During the last thirty years our knowledge of physiology has advanced all along the line. We can now form a mental picture of every event occurring in the heart throughout the cardiac cycle. We know the nature of the impulses and the course of the nerves concerned in the multitudinous adaptations of the circulation to every change in the environment of the body or of the activities of its different organs. We can form a connected image of the chain of processes concerned in the digestion of food during its passage through the whole alimentary canal.

The localisation of function in the central nervous system, to which in 1875 Ferrier had already contributed his remarkable experiments on localisation in the cerebral cortex, has now been extended to the whole nervous system. Though in such a complex system many paths must be still unknown, experiment has enabled us to unravel much of its complex character, and to form a clear conception of the possible paths open to almost any impression which may play upon the surface of the body. Comprehension of the coordination of movement, and of the processes involved in every movement of a limb, has only lately been revealed to us by the researches of Sherrington. An examination of medical literature shows us that the clinical physicians are alive to the close connection which exists between the study of disease and the study of physiology. Every new fact in physiology is tested with reference to the conditions in disease. Although in many cases the observations on man are too inexact to enable a complete utilisation of the facts of physiology, yet these clinical methods are being improved day by day, and the science of medicine is taking a larger and larger part as a guide to the practice of the art.

In his evidence before the Commission, Sir John Burdon-Sanderson expressed his profound conviction that "A future will come—it may be a somewhat distant future—in which the treatment of disease will be really guided by science. Just as completely as mechanical science has come to be the guide of the mechanical arts, do I believe and I feel confident that physiological science will eventually come to be the guide of medicine and surgery."

There is a danger that the striking utilitarian success gained by the pursuit of experimental investigations along certain definite lines may encourage the fallacy that any true distinction can be drawn between utilitarian and scientific researches. Even now a clamour has been raised by certain agitators for a restriction of experiments to those which can be shown to have a direct utilitarian object. Such a restriction is impossible. Science has taught us again and again that any increase in our knowledge must finally add to our powers. The so-called purely scientific researches are those dealing with general relations, and have as their object the discovery of laws which must affect our conceptions of the science in a number of its ramifications. It is the purely scientific researches which have effected the greatest revolutions in man's relation to his environment, and have placed within his hands the largest powers of control. Moreover, these researches must be undertaken in a spirit of pure curiosity, from a love of knowledge itself. The man who is always seeking a practical outcome for his experiments will have his field of vision narrowed, and the scope of his researches limited thereby.

The present Commission has been appointed largely as a result of an agitation on the part of those by whom every advance in science, and every change in the relations of man to his surroundings, are regarded as improper or even impious, and these persons, by misleading statements appealing to the better feelings of a credulous and unlearned public, have succeeded in arousing a feeling of resentment against those who are engaged in the advancement of the science of life by experiment. There can be no doubt that a marshalling by the Commission of the true facts of the case will show the slender grounds for the allegations made by the anti-scientific agitators, and will demonstrate the remarkable benefits to man attained during the last thirty years at the cost of the infliction of a trifling amount of pain on some animals.

It has been said, with truth, that the amount of pain inflicted in all the laboratories in this country in the course of a year is not equal to that suffered by the birds in one day's shooting *battue*, carried out, not primarily for food or for the benefit of man, but to amuse a few rich men. Yet noble "sportsmen" take a prominent place among the patrons and vice-presidents of the various anti-vivisection societies which, by leaflets and paid lecturers and letters to the Press, disseminate misleading and lying statements throughout the country in furtherance of their malignant campaign against science. Mr. Paget has been well advised in appending to this new edition a part iv., entitled "The Case against Anti-vivisection," in which he deals at some length with the unscrupulous methods of these societies and of their paid agents. It is sincerely to be hoped that the Royal Commission will inquire, not only into experiments on animals, but also into the morality of the anti-vivisectionists themselves.

E. H. S.

SENSE-PERCEPTION IN GREEK PHILOSOPHY

Greek Theories of Elementary Cognition from Alcmaeon to Aristotle. By John I. Beare. Pp. viii+354. (Oxford: Clarendon Press, 1906.) Price *12s. 6d.* net.

THIS volume, from the pen of the regius professor of Greek in Dublin, continues the kind of work so well begun for English readers by Prof. Burnet's "Early Greek Philosophy." It deals with the various theories entertained in regard to the five senses, sensa-

tion in general, and lastly the Sensus Communis, and its method is under each head to give as consistent a view as possible of what was severally taught by Alcmaeon, Empedocles, Democritus, Anaxagoras, Diogenes of Apollonia, Plato, and Aristotle There is little or no attempt to criticise these writers from the standpoint of modern philosophy But the statement is very clear, the discussion of disputed points scholarly, the facts are well arranged, and the literature—to judge from the footnotes and the list of books consulted—seems to have been thoroughly studied although one misses a reference to one recent work on the "De Anima"—that of Rodier, whose commentary, if not his translation, has been regarded by competent judges as indispensable.

As dissection was practised as early as Alcmaeon—he is stated to have been a pioneer in this direction—there is perhaps room for our wonder that the Greeks did not in their swift way attain some more consistent and conclusive theory regarding the working of the senses and the nervous system as a whole Possibly they were encumbered with the armour of pre suppositions with which they went forth to encounter nature—Empedocles and Anaxagoras with their respective doctrines that like is perceived by like, and contrary by contrary, Aristotle with his antitheses of form and matter, of *dynamis* and *energeia*, nearly all of them with a disposition—to which Aristotle, worse advised than Plato, succumbed—to regard the heart and not the brain as the physical centre of the intellectual life But at the same time one notes in this volume how little right we have to throw stones at them, *e g* how modern physics (to quote Prof Beare's words) "is as helpless to explain colour as physiology to explain olfactory function," or, again, that "the psychology of taste has advanced little beyond the popular and superficial stage at which Alcmaeon left it" Still, when all is taken into account, the final impression is one of admiration for the insight—which is genius—of an Aristotle, *e g* when "he rejected as if by anticipation the Newtonian emission theory of light", for the skill, too, with which he could produce a theory that would do justice to all the valuable elements in earlier philosophy, *e g* when he harmonised Empedocles and Anaxagoras by his statement that perception is a relation in which what was unlike becomes like

The occasional inconsistencies in Aristotle—those spots in the intellectual sun—are well discussed by our author Aristotle's views, or possible views, on biological development have always been a difficult, if interesting, subject, for in one passage of the "De Sensu" the master rejects Democritus's account that each of the other senses is "a kind of touch", but while Dr Ogle, on the ground of that passage, hesitates to credit Aristotle with the belief "that the remaining special senses are but modifications of touch or general sensibility," Prof Beare, on the other hand, finds it "hard to suppose that Aristotle—the pioneer, in *general* terms, of the theory of evolution not only physical but physiological and psychological—should in this particular application of his theory have failed to recognise it, or have denied its truth simply because it was a doctrine of Democritus" On every account this volume is to be commended to those interested in the development of theories of sense-perception

GRAVITATIONAL ASTRONOMY

The Collected Mathematical Works of G W Hill Vols ii, iii Vol ii, pp v+339, vol iii, pp 577 (The Carnegie Institution of Washington, 1906)

THE second and third volumes of Hill's works carry to 1890 the republication of his papers prepared for the American ephemeris and his miscellaneous writings The latter volume, which is entirely devoted to the theory of Jupiter and Saturn, is probably without parallel as a piece of calculation It is a splendid and enduring monument to ten years' incessant labour, and the nicety of agreement of its predictions with observation continues to justify the pains spent upon it It replaced Leverrier's theory, which was published while this was in course of production, and Hill found himself unable to point to any definite omission or flaw in Leverrier's theory which would account for the much inferior accuracy of its results, it seems to be due to accumulation of almost impalpable differences, and if some of Hill's work strikes one as over-elaborated, one can always look to the "Theory of Jupiter and Saturn" for justification

At the same time, one cannot help feeling in turning over some of these papers that to an adept straightforward calculation becomes an end in itself The memoir, No 48, on the lunar inequalities due to the spheroidal figure of the earth is an example This is entitled also a supplement to Delaunay's theory of the moon The theoretical additions are fairly obvious, and the main part of 143 pages is occupied with the steps required for determining 165 terms in the moon's longitude and 209 in latitude which are factored by the earth's ellipticity Not the fiftieth part of these terms reaches 0″ 1 in amplitude, and not the tenth of 0″ 01 Most people will regard this as more striking in its proof of the author's colossal patience than in any other quality

Probably no writer of the same originality has been content to follow his predecessors' models, upon occasion, so closely as Hill They owe him much The paper referred to above is the most elaborate application of Delaunay's method outside Delaunay's own work Hill's "Jupiter and Saturn" is the greatest monument in existence to the power of Hansen's methods, Hansen's own Lunar Theory not excepted It was to the problem of these two great planets that Hansen first made serious application of his methods in 1831 But, as Hill puts it, he "seems to have been carried away by the ambition of applying his method of treatment to the lunar theory," and never returned to it If anyone would disabuse his mind of the common misapprehension that Hansen's ideas are uncouth and his methods formless, and gain at the same time a concrete view of Hansen's method, he could not do better than follow out the steps of the *Auseinandersetzung* as applied by Hill Hill's modifications, few though important, are no obstacle The truth be-

comes patent that Hansen was a master of beautiful mathematical device. The bewildering detail ceases to obscure it when put into arithmetical form.

The problems of exact solution of the secular perturbations and of finding integrals of the equations of motion, which hold good for indefinite spans of time, must in the future occupy more and more attention.

Lately Hill has published an important memoir upon the subject (*Astronomical Journal*, vol. xxv.), two papers, Nos. 37 and 47, in the present volume show that his interest is not of recent date. No. 41, "Reply to Mr. Neison's Strictures on Delaunay's Method," shows him as a critic—a formidable though reserved antagonist not without ironic humour. No. 44, "On the Interior Constitution of the Earth as Respects Density," is a beautiful example of what he can do when working without the fetters of exact astronomy. Eventually the paper is a solution of the well-known equation for the density of a spherical aggregation of gravitating gas at constant temperature. The question had been treated before, but Hill's method is out of all measure more striking and complete than had been given previously.

NEOLITHIC MAN

Neolithic Man in North-East Surrey. By Walter Johnson and William Wright. With a chapter on Flint by B. C. Polkinghorne. Cheaper re-issue. Pp. viii+200. (London: Elliot Stock, 1906.) Price 3s. 6d. net.

THIS book is the result of several years of archæological investigation in the north-east corner of Surrey. The area visited measures about 14½ miles by 13 miles, it would fall between the Thames on the north and a line drawn between Boxhill and Oxted on the south. Within these limits the researches of our authors have been patient and unwearying, they have sought for traces of Neolithic man in field after field, on height after height. Set down in their pages is a large amount of information as to his homes (Worms Heath, Croham Hurst, Barrow Hill, &c.) and burial-places, as to his methods of work, agricultural and domestic, as to the food he ate and the implements he used, celts, hammer-stones, arrow-heads, scrapers, &c. Some space too has been devoted to his track-ways and fortifications, in most cases the same ground was occupied at a later period by Roman roads and works, or those of other invaders less skilled in engineering.

The main subject is prefaced by an account of the various inhabitants who have succeeded one another in this country, especially the Neolithic and bronze-using peoples, and by a survey of the geological features of Neolithic Surrey. Our authors are certainly right in holding that the "ages" overlapped or merged into one another, the terms "Stone, Bronze, Iron age" are, in fact, merely conventional; they can only be applied to the phases in development during which stone, bronze, or iron began to be worked, side by side with the material already in use, not of necessity replacing it. In Lancashire, for example, where the hills to the north prevented ready retreat in that direction, stone, bronze, and even iron seem to have been used contemporaneously at one period (see "Victoria County History of Lancashire"). Generally speaking, these opening chapters are highly instructive and accurate, they form a useful introduction to the story of Neolithic man. If they have a fault it is that they are perhaps a trifle too technical. Being a cheap re-issue, the present edition is obviously intended for the local student, to whom—not, of course, to the specialist—this preliminary information might be expected to be of service. In these circumstances the authors might have done better to leave out words like artifact, homotaxial, &c.; even geological terms like patina and Pleistocene, or at any rate to give their meaning. To leave them unexplained is to presuppose knowledge which is only too often to seek.

We have neither the space nor the necessary local knowledge to enter into a detailed criticism of the main subject. If we may venture a suggestion, we should recommend greater caution in the use of arguments based on etymology. We doubt very much whether all the authors' results (*e.g.* in chapter x.) would stand the scrutiny of a trained philologist. Only those who have made a special study of place-names are able to realise how dangerous and misleading this kind of evidence is apt to be.

There can be no question that the book is a valuable one. The extent of general knowledge displayed in it, and its high standard of scholarship, place its authors far above the ordinary run of local archæologists. Their work is only popular in the sense that it is inexpensive. In addition to the maps and illustrations by Sidney Harrowing and Frank Percy Smith, it has an index and a list of the authorities referred to in each chapter. Mr. B. C. Polkinghorne contributes a supplementary chapter on the constitution and alterations of flint, with reference to the subject of flint implements.

OUR BOOK SHELF

In the Days of the Comet. By H. G. Wells. Pp. 305. (London: Macmillan and Co., Ltd., 1906.) Price 6s.

THOUGH the actual collision of the earth with the head of a comet is an extremely improbable event, it is not beyond the bounds of possibility. In 1861 the earth passed through the tail of a comet; and the showers of meteors occasionally observed near the end of November are probably due to encounters with fragmental remains of Biela's lost comet. The disc-like appearance of Holmes's comet in 1892 gave rise to the suggestion that the comet was approaching the earth head-on, and we believe Mr. Wells then used the idea in one of his clever short stories. In any case he would have no difficulty in finding justification for the supposed collision with a comet which forms the *deus ex machinâ* of the present romance.

The comet which springs from Mr. Wells's imaginative brain is seen in its early days by an enthusiastic amateur astronomer who forms one of the minor characters of the story as a "quivering little smudge of light among the pin-points," while the spectroscope showed "an unprecedented band in the green." The unknown element which this peculiar green radiation

represented proves to be the Divine afflatus that lifts the human race out of selfish individualism into socialism understood in its finest sense The struggle for existence and the survival of the fittest no longer express operations of natural law, and the world becomes a place where the prevailing spirit is "all for all and each for each." Love is transfigured, hate perishes, war and all other manifestations of our animal nature are rendered unthinkable after the earth has passed through the comet The change which evolution can scarcely anticipate in the distant future is brought about in a single night

The idea is a noble one, and Mr Wells has dealt with the phenomenal and sociological aspects of the transformation in a masterly manner What is the destiny of the human race cannot yet be foreseen, but what man might become when "a new heaven and a new earth" have been created is a worthy subject of speculation, and when the theme is developed, as it is in this book, with scientific knowledge, prophetic insight, lofty purpose, and human sympathy, it almost persuades us that the gospel it conveys points the way to the millennium The message may not be understood, but the story in which it is presented cannot fail to excite interest and stimulate thought

The Elements of Chemical Engineering By Dr J Grossmann, with a preface by Sir W Ramsay, K.C.B, F.R.S Pp viii+152 (London C Griffin and Co, Ltd, 1906) Price 3s 6d net

It can scarcely be said that our system of technical education is satisfactory, so far as chemical technology is concerned Our technical colleges and universities turn out annually a large number of students who have received a fairly good training from the theoretical point of view, but have very little knowledge of apparatus or processes as conducted on the manufacturing scale It is obviously impossible for teachers who have not themselves been engaged in factories to teach chemical technology successfully Our German competitors have fully realised this, and some of the larger chemical manufacturers have combined and founded an institution specially devoted to the education of teachers, all the operations being carried out on the manufacturing scale In the absence of some educational establishment of this kind we must assume that the education of most of our students is defective from the practical point of view, and means must be found to convey the requisite knowledge before they can be entrusted with the supervision of manufacturing operations

Dr Grossmann's book has been specially written with this end in view, the object of the author being to make the student familiar with those factory appliances which are the equivalents of the apparatus used in the laboratory To render the comparison still more easy, the plant described is classified according to the supposed laboratory appliance which it represents. It is not always easy to ensure parallelism under such an arrangement, for instance, the chapter on "The Funnel and its Technical Equivalents" deals mainly with filtration, which is not the primary function of a funnel The remarks on the materials used in chemical engineering are practical, and will be of great use to students, whose knowledge on this subject is usually very defective

Among the useful features in which this work differs from similar manuals may be mentioned the price list of chemicals, which will be of great service to beginners, although, as Dr. Grossmann rightly remarks, the prices are liable to frequent fluctuations How great these fluctuations may be is shown by the fact that copper is now twice and antimony three times the price quoted in the list The price given for amyl acetate, 4l. 14s. 6d per lb, is evidently an error

As Sir William Ramsay says in his preface, the author has given a simple and lucid statement of the difficulties that a student may expect to meet with, and the book may be recommended as an introduction to the practical work of the factory

Crystal Gazing Its History and Practice, with a Discussion of the Evidence for Telepathic Scrying By Northcote W Thomas With an introduction by Andrew Lang Pp xlviii+162 (London Moring, Limited, 1905) Price 3s 6d net

The practice which gives its name to this book is only one of a number of devices which have been employed to assist the appearance of visual hallucinations Mr Thomas gives a popular account of the various methods which have been used in classical, mediæval, and modern times and describes the practices of various savage or barbarous peoples, such as the use of blood by the Maories and Pawnees, of quartz by the people of Sarawak, and of mirrors by the members of more advanced races

The subject has two distinct aspects One deals with the nature of the psychological processes involved in the appearance of the visions, and, treated from this point of view, crystal gazing is brought into line with other psychological processes such as visual imagination, hypnogogic and hypnotic illusions and hallucinations, &c

The other aspect deals with the question whether the visions of the scryer provide any evidence in favour of telepathy On this aspect Mr Thomas gives accounts from many sources, and concludes that, though fragmentary and unsatisfactory, the evidence is, on the whole, in favour of telepathic crystal visions It must be pointed out, however that his data provide perhaps equally strong evidence in favour of prophetic scrying The book has an introduction in which Mr Andrew Lang gives an account of the circumstances which first led him to take an interest in crystal gazing and of many experiments with which he has had to do Mr Lang regards his own ventures in this field as those of an amateur, and he appeals to professed psychologists to undertake the further investigation of the subject His own attitude however, is so eminently judicial that it is a matter for regret he cannot himself give more attention to this line of work, for the judicial mind is not too common either in the more academical or the more amateur students of this field of research

The History of the Collections contained in the Natural History Departments of the British Museum Vol ii, Separate Historical Accounts of the Several Collections included in the Department of Zoology Pp 782 (London British Museum, 1906) Price 30s

In this volume officers of the various sections of the Zoological Department have given accounts of the collections under their respective charge, tracing the evolution of each from small beginnings to its present condition Each account is complete in itself, but a remarkable degree of diversity is noticeable in regard to the amount of space occupied by the different histories, the notice of the bird collection far exceeding all the others in length At the end of each account is a biographical list of the various donors and collectors who have contributed to the section This involves a large amount of repetition, and some discrepancies are noticeable when the different lists are collated In many portions of the volume the editorial blue pencil might have been used freely with great advantage, and in some places the prolixity is so great that it is exceedingly difficult to winnow out the grain from the chaff Nevertheless, the volume contains a great mass of valuable information with regard to

the progress of natural history in this country and the evolution of the collections in the Museum which it would be very difficult, or impossible, to obtain elsewhere. Despite a lamentable loss of early collections, like those formed during Cook's voyages, owing to lack of knowledge of their value and indifferent curatorship, the Museum is particularly rich in type-specimens, more especially of species presenting well-marked characteristics of their own. In many cases particular attention is directed to these and other specially interesting specimens in the collection, although in these matters, again, a great diversity of treatment is noticeable in the different accounts.

Science and Religion. By the Rev. Lord William Gascoyne Cecil. Pp. 105. (London: Hodder and Stoughton, 1906.) Price 3s. 6d. net.

Five addresses delivered in substance at St. Lawrence Jewry during Lent, together with an explanatory foreword, make up the contents of this volume. The author lays claim to "no scientific qualifications at all," and therefore "can only speak as one of the crowd," to use his own description of himself. The sermons follow lines which are already familiar to students of science acquainted with the literature which has grown up round the attempt to "reconcile" traditional theology with results of scientific study.

How to Learn on Shore the Rule of the Road at Sea. By E. W. Owens. Pp. 40+23. (London: George Philip and Son, Ltd., 1906.) Price 3s. 6d. net.

This excellent little book meets a great want, and is strongly recommended for use in all training schools and ships. It is arranged in a convenient manner, and the explanations are simple and good. Part ii., which consists of extracts from the Merchant Shipping Act and the latest regulations for preventing collisions at sea, special lights for fishing craft, &c., makes the book not only useful in the class-room but a great convenience on the bridge of any ship as an *aide mémoire*. H. C. Lockyer.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Absorption of the Inert Gases by Charcoal.

It may interest some of your readers to know that Prof. Rutherford, in a private letter addressed to myself, has given a full explanation of the circumstances that led him to infer that the absorption of the inert gases by charcoal was exceptional. Fully appreciating the difficulties that beset Prof. Rutherford at the time he wrote the letter to Nature (vol. lxxiv., p. 634, October 25), I exonerate him from all blame in the matter, and willingly cancel all the expressions of regret he has been pleased to make.

With regard to the latent heat question, I ought to mention that Prof. Rutherford will not commit himself to the view that the electrometer readings recorded in the paper I quoted are proportional to the partial pressures of the emanation. He says:—"I do not know how far the electrometer readings may be taken as a measure of the partial pressures of the emanation, but naturally measurements over a range of temperature of 1° or 2° cannot be vouched for with any certainty." This would be a strong criticism provided any manometric measurements had been attempted, but if the electrometer measures directly the relative concentration of the emanation in a given volume of gas, the method is so sensitive that the increase caused by a narrow range of temperature is less liable to error. It is clear, however, that new determinations will have to be made before the question can be settled.

In the meantime, I can only wish Prof. Rutherford success in the applications of charcoal to the study of the emanations of radio-active bodies, and take the opportunity of expressing my gratification at seeing charcoal becoming of such scientific utility in the hands of workers like the Hon. R. J. Strutt, the French chemists Moureu and Biquard, not to mention others; the more especially as my own labours have been interrupted for reasons given in my former communication.

James Dewar.

Royal Institution, 21 Albemarle Street.

Radium, Actinium, and Helium.

In Nature of November 29 Dr. B. Walter discusses the theory of Prof. Rutherford that in radio-active change accompanied by the emission of an α particle the atomic weight is diminished by 4, the atomic weight of helium. According to this assumption, the transformation of uranium (238·5) into radium (225) is due to the loss of *three* helium atoms. Now uranium gives one α particle in changing to uranium X, so that only two such changes remain for any subsequent transformations. If we accept the result of Profs. Moore and Schuldt (*Phil. Mag.*, October) that uranium X gives out α rays, two changes are accounted for, and only one is left for intermediate products.

In Nature of November 15 Mr. Boltwood brings forward experimental evidence in support of the view that actinium is an intermediate product between uranium and radium; but in the case of actinium and its derivatives four changes, accompanied by the emission of α particles, occur. Thus, on the assumption that the α particle is a helium atom, there is no room for these products.

The difficulty can be removed by adopting another alternative, suggested by Prof. Rutherford, that the α particle is *one-half* of the helium atom carrying a single ionic charge (*Phil. Mag.*, p. 366, October). In this case we should have the following series possible:—

Series I.	*Series II.*
Uranium (238·5)—α	Uranium (238·5)—α
Uranium X (236·5)—α, β, γ	Uranium X (236·5)—α, β, γ
Actinium (234·5)	Unknown (234·5)—α
Radio actinium (234·5)—α	Actinium (232·5)
Actinium X (232·5)—α	Radio actinium (232·5)—α
Actinium emanation (230·5)—α	Actinium X (230·5)—α
Actinium A (228·5)	Actinium emanation (228·5)—α
Actinium B (228·5)—α, β, γ	Actinium A (226·5)
Unknown (226·5)—α	Actinium B (226·5)—α, β, γ
Radium (224·5)	Radium (224·5)

If the atomic weight of radium were 226·5, the unknown change accompanied by the expulsion of an α particle must be removed from the series. One or more rayless changes may also occur.

It is interesting to note that the atomic weight of actinium, according to Series II., comes out as 232·5, that is exactly the atomic weight of thorium. These two substances closely resemble one another in their radio-active properties, giving transformation products of very similar character. This suggests as an analogous case the similarity between nickel and cobalt, two elements of practically the same atomic weight. H. S. Allen.

King's College, London, November 30.

Mira Ceti.

It may be well to note that this variable star is exceptionally bright at its present maximum, the magnitude being about 2·0. As usual when the star is bright, it is less red than its average. T. W. Backhouse.

West Hendon House, Sunderland, December 1.

A GEOLOGICAL HISTORY OF DEVONSHIRE[1]

THE title of this book requires some explanation, for the subject-matter is not a description of the existing scenery of Devon, or of the manner in which its various features have been developed out of the rock-surfaces which last rose above the sea It is mainly a description of the physical and geographical conditions under which the rocks of the south-west of England were formed, it is an endeavour (as indicated by the subtitle) to follow the geographical evolution of the region, and to picture the successive stages in the development of its physical geography

The aim of the author has evidently been to present what is known of the geological history of Devonshire in as interesting a form as possible, hence, as stated in the preface, he has used "the minimum of technical language with the object of making them (his pages) suitable for the beginner and the ordinary reader who has no previous knowledge of the subject, but who cares to know how Devonshire came to be what it is"

Moreover, he has contrived to include much general information regarding the rocks of the British Islands, and since many modern geologists consider that professorial teachers of geology have dwelt too much on the lithological and structural branches of the science, and too little on its connections with physical geography, such a book as this ought to find a welcome in many quarters

After an introductory chapter devoted to "Protozoic" time, "we reach the date when the history of Devon begins to be readable from its own records," this, of course, being the Devonian period Having first indicated the probable geography of Britain at this time, the author describes the rocks of North Devon, indicating the great compression and contortion to which they have been subjected He mentions the diverse views which have been held regarding their succession, and wisely remarks that further investigation is required before this matter can be settled

The next chapter is devoted to the Devonian of South Devon, of which a good description is given, with a glance at the schistose area of the Start laying stress on the fact that the results of compression and metamorphism become greater in the direction of these crystalline rocks It was perhaps to be expected that he would repeat the statement that the Devonian limestones are essentially of coralline origin, and are to be regarded as ancient coral-reefs, for he could quote a recent Geological Survey memoir to that effect Nevertheless, its truth has more recently been questioned, and it has been shown that large parts of the limestone are crinoidal, while others are chiefly made up of Stromatoporoids, moreover, we do not know whether any Palæozoic corals were reef-builders

FIG 1—The Haven Cliff, Axmouth Greensand on eroded surface of Keuper Marls From The History of Devonshire Scenery

In chapter vi we find a general account of the Carboniferous rocks before coming to those of Devon, the description of which is not very satisfactory because it is entirely based on the old view that the Coddon Hill cherts overlie the limestones and that the whole group represents the lowest part of the Carboniferous Limestone of Bristol and South Wales, whereas good reasons were given by Dr W Hind in 1904 for placing the cherts below the limestones and for regarding both as the equivalents of the Pendleside

[1] "The History of Devonshire Scenery—An Essay in Geographical Evolution By A W Clayden Pp 202, with 41 photographic illustrations and some diagrams. (Exeter J G Commin, London Chatto and Windus, 1906) Price 10s 6d net

beds which overlie the great mass of the midland Carboniferous Limestone.

For the next two chapters we have nothing but commendation. They deal with the time represented by the great gap between the Culm and the Permian rocks. The first is entitled "The Great Upheaval," and gives a clear and sufficient account of the post-Carboniferous mountain-ranges which are known as the Hercynian or Armorican system, and of the subsidiary Pennine range. This is illustrated by a restoration of the physical geography of the British area at this time. The succeeding chapter is devoted to volcanic rocks, with especial regard to the Carboniferous and post-Carboniferous volcanoes.

In the discussion of the Dartmoor granite in chapter vii. the author is faced by a problem which has given rise to many diverse expressions of opinion. He practically adopts the view advocated by the late R. N. Worth, and sets himself to show "that the granite mass of Dartmoor is really the solidified upper part of the cooled lava reservoir from which the Carboniferous volcanoes of Devon were fed." We think he states the case for this theory with somewhat of over-confidence, for the dissolving of sedimentary rock in the granitic magma is thought by some to be very improbable, and the temperature at which the granite solidified is still a disputed point, while the actual evidence for the existence of volcanoes over the Dartmoor granite is by no means strong. Prominence is, of course, given to the occurrence of peculiar volcanic rocks in the Permian breccias, the origin of which is also dealt with in this chapter.

In the chapter on the "Salt Lake Period" (chapter viii.), an excellent account is given of the Devon Trias and of the conditions under which its successive beds were deposited, the proofs of its salinity and of its barren desert-surroundings being well brought out. The illustrations, too, are especially good, including photographs of "red marl with salt-crystals," "the base of the Budleigh pebble-bed," and "the tea-green marls overlain by the Rhætic bone-bed."

The dawn of Jurassic time and the great climatic change produced by the irruption of the sea into the salt lake are set forth in the opening page of a chapter entitled "The Age of Reptiles." In this the Lias and the Liassic sea are duly described, and the subsequent sequence of Jurassic rocks is briefly indicated, with some remarks on the erosion to which the surrounding land must have been exposed during the whole period, and especially during its closing scenes, when the British area was again upraised, and the sea retreated far to the south and north-east.

Under the title "The Return of the Sea," chapter x. deals with the beginning of the great Cretaceous subsidence. The stratigraphy of the Gault and Greensand is briefly but clearly described, and there are excellent views of the two cliff sections near Seaton Haven cliff and Whitecliff, the former of which we have selected as an example. Then follows a chapter on "The Chalk," in which the peculiar Devon development of an arenaceous Cenomanian overlain by Middle Chalk and a portion of the Upper Chalk is fairly well described. We notice, however, that there is no mention of the "Beer Stone," another Devon speciality, which differs greatly from ordinary chalk and has been largely used as a building stone from Norman times to the present day.

Mr. Clayden appears to be unaware of the views published in the Geological Survey memoir on the Cretaceous rocks of Britain respecting the physical conditions under which the different parts of the Chalk were accumulated. When, therefore, he observes that the facts "are inconsistent with the idea of a deep sea," and assumes that the Chalk (as a whole!) was formed "in a shallow sea perhaps less than 100 fathoms deep," we can only express our surprise.

Chapters xii. and xiii. deal with Eocene time, describing the "Plateau Gravels" and the Bovey deposits, which latter the author considers to be essentially lacustrine, and to have been formed in "the Bovey lake." Chapter xiv., entitled "The Rivers of Devon," is the most original portion of the book, and we only wish that the author had developed this subject at greater length. When we say that he believes the drainage of the whole of northern and central Devon in early Tertiary time to have been carried off by one great river flowing eastward, it will be obvious that such a supposition raises many interesting questions. We are inclined to regard it as a very probable theory, but undoubtedly its details require fuller consideration than he gives them.

The modern scenery of the county, how it is partly an uncovered Permian surface and partly one carved out of an Eocene peneplain, is briefly described in the final chapter. Dartmoor also comes in for further mention, and its type of scenery is well illustrated, as will be seen from the illustration selected.

FIG. 2.—The Crown of the Moor: Yes Tor. From "The History of Devonshire Scenery."

In conclusion it may be said that Mr. Clayden has succeeded very well in the accomplishment of his general intention. The book appeals to a much wider circle than the few readers who may be found in Devon and Cornwall. It really treats of the whole of southern England from Dover to Bude, and should be in the hands of all those who are interested in the geology and the physical geography of our southern counties.

THE UNCIVILISED CHILD.[1]

"THE explanation is rather artistic than scientific"—so the author admits about what he has written on the origin of the "couvade." It is a way of saying that he has found his explanation does not accord with the facts gathered by anthropologists concerning this custom. Such is the keynote of the

[1] "Savage Childhood: a Study of Kafir Children." By Dudley Kidd. Pp. xvi+314. (London: Adam and Charles Black, 1906.) Price 7s. 6d. net.

book; it is artistic rather than scientific It is a life-history of the Kafir child, an excellent record of many facts concerning customs, practices, games, songs, sayings; and it may be particularly commended for the number of capital photographs which illustrate it But the scientific possibilities in all this field of observation have been practically untouched The Kafir baby has not been studied from the Darwinian standpoint, the superstitions which affect him have hardly been looked at with the folklorist's knowledge, racial customs and practices have scarcely been viewed in the light of anthropology

One must have expected to find in savage children many instances of those Simian characters which have been noted among European children, even—because the Kafir child is on a lower scale—to find them more pronounced But the author says nothing about them, and his photographs give very little in this way One picture—it is the frontispiece in the book—shows a shy child, who has instinctively assumed an attitude of self-defence, and has its arm raised as if to ward off a blow, and especially to protect the eyes Now, as fear is the natural basis of shyness, this attitude is very happy It is an inherited instinct, no doubt, but not necessarily Simian, yet if the author had been on the watch for exhibitions of inherited instinct he would certainly have obtained many which were truly Simian in their origin

Had the author been more fully acquainted with folklore results he would not show so many doubts about accounting for various customs For instance, he notices (pp 41, 42) the practice of a Kafir mother protecting her child by leaving a ring of her milk round it, or by squeezing "a few drops of her milk on to its head" He suggests two explanations, but from folklore research he could learn that the second is more nearly correct—that the milk forms a connecting link with the mother, or, rather, that the milk is actually the mother herself present As Mr Hartland says in discussing the life-token, "the external object is believed to be, or to contain, a part of the man himself" ("Legend of Perseus," ii, p 51) The word "part" there is hardly sufficient The external object, the detached portion of a person, or anything which has absorbed a portion of a person, is believed to be more than a part it is rather looked on as the *alter ego*, subject to all his disabilities, endowed with all his potentialities, and just as destruction of the *alter ego* involves destruction of the *ego*, the very basis of witchcraft, so the power to watch and ward, which the *ego* possessed, is supposed to be also inherent in the *alter ego* The mother's milk is as capable a protector as the mother herself

The basis of the same superstition—that a part of self is the other self—is further illustrated by the author in "Confusion of Self with the Clothing and Possessions," "with the Shadow," "with the Picture," "with the Name," and so on (pp 66 *et seqq*), and he gives quite the right explanation of these The man's shadow is but another form of himself, and anything done to his shadow is done to him The "native doctors apply medicine to people's shadows as well as to their bodies" (p 70), that is, application to the shadow is quite as efficacious as to the body So a man refused to be photographed, because the person having the photograph would have a hold on him (p 71)

The secret burning of the child's sleeping mat (p 84) is another case The mat is burnt to prevent it falling into the hands of any evil-disposed person, who could then work ill on the child Here we have the apparent contradiction that meets us in such customs One would at first think that the destruction of the mat would mean the killing of the child So it would, if done with evil intent, because the intention with which an action is done makes all the difference

To conclude, one may quote some admirable remarks of the author on the unfortunate result of ignorant European interference with Kafir customs When it is considered how terrible a failure individualistic civilisation is, at any rate for some millions of our population, and that the remedy is declared to be Socialism, it is quite possible to echo the author's protest against forcing individualism on people who appear to have got great enjoyment out of life under Socialism The author says (p 129),

FIG 1—Boys playing "King of the Castle" on an ant heap near the Zambezi From "Savage Childhood," in which the photo is about an inch longer and wider than this illustration.

"While English magistrates are above suspicion as to the justness of their decisions from a Western point of view, yet the natives complain not a little concerning the injustice of our government In olden days no Kafir felt it to be unjust on the part of a chief to make his subjects work for white men, and yet give their money to him (the chief) To Europeans this is essentially unjust, for it is an infringement of the rights of the individual To the native the rights of the corporate clan are vastly more important than those of the individual Consequently, when in

interest in it" A little more discretion on the part of readers of papers in having regard to the composition of their actual audience would be helpful here In some cases experimental illustration would bring home to a larger number what is followed with difficulty from a merely verbal statement But I am afraid that no complete remedy is within reach.

Increase of specialisation, however inconvenient in some of its aspects, is, I suppose, a necessary condition of progress Sometimes a big discovery, or the opening up of a new point of view, may supersede detail and bring unity where before there was diversity, but this does not suffice to compensate the general tendency Even in mathematics, where an outsider would probably expect a considerable degree of homogeneity, the movement towards diversity is very manifest Those who, like myself, are interested principally in certain departments, and can look back over some forty years, view the present situation with feelings not unmixed It is disagreeable to be left too far behind Much of the activity now displayed has, indeed, taken a channel somewhat remote from the special interests of a physicist, being rather philosophical in its character than scientific in the ordinary sense Much effort is directed towards strengthening the foundations upon which mathematical reasoning rests No one can deny that this is a laudable endeavour, but it tends to lead us into fields which have little more relation to natural science than has general metaphysics One may suspect that when all is done fundamental difficulties will still remain to trouble the souls of our successors Closely connected is the demand for greater rigour of demonstration Here I touch upon a rather delicate question, as to which pure mathematicians and physicists are likely to differ However desirable it may be in itself, the pursuit of rigour appears sometimes to the physicist to lead us away from the high road of progress He is apt to be impatient of criticism whose object seems to be rather to pick holes than to illuminate Is there really any standard of rigour independent of the innate faculties and habitudes of the particular mind? May not an argument be rigorous enough to convince legitimately one thoroughly imbued with certain images clearly formed, and yet appear hazardous or even irrelevant to another exercised in a different order of ideas? Merely as an example, there are theorems known as "existence-theorems" having physical interpretations, the object of which is to prove formally what to many minds can be no clearer afterwards than it was before The pure mathematician will reply that, even if this be so, the introduction of electrical or thermal ideas into an analytical question is illogical, and from his own point of view he is, of course quite right What is rather surprising is that the analytical argument should so often take forms which seem to have little relation to the intuition of the physicist Possibly a better approach to a reconciliation may come in the future In the meantime we must be content to allow the two methods to stand side by side and it will be well if each party can admit that there is something of value to be learned from the point of view of the other

In other branches at any rate, the physicist has drawn immense advantage from the labours of the pure analyst I may refer especially to the general theory of the complex variable and to the special methods which have been invented for applying it to particular problems The rigorous solution by Sommerfeld of a famous problem in diffraction approximately treated by Fresnel, is a case in point We have moved a long way from the time when it was possible for the highest authority in theoretical optics to protest that he saw no validity in Fresnel's interpretation of the imaginary which presents itself in the expression for the amplitude of reflected light when the angle of incidence exceeds the critical value In this connection it is interesting to remember that, in his correspondence with Young, Laplace expressed the opinion that the theoretical treatment of reflection was beyond the powers of analysis The obvious moral is that we are not to despair of the eventual solution of difficulties that may be too much for ourselves

As more impartially situated than some, I may, perhaps, venture to say that in my opinion many who work entirely upon the experimental side of science underrate their obligations to the theorist and the mathematician. Without the critical and coordinating labours of the latter, we should probably be floundering in a bog of imperfectly formulated and often contradictory opinions. Even as it is, some branches can hardly escape reproaches of the kind suggested I shall not be supposed, I hope, to undervalue the labours of the experimenter. The courage and perseverance demanded by much work of this nature is beyond all praise, and success often depends upon what seems like a natural instinct for the truth—one of the rarest of gifts

Copley Medal

The Copley medal is awarded to Prof. Elias Metchnikoff, For Mem R S, on the ground of his distinguished services to zoology and to pathology, particularly for his observations on the development of invertebrates and on phagocytosis and immunity From 1866 to 1882 Prof Metchnikoff's work was exclusively zoological, and mainly during that period he produced a series of brilliant memoirs dealing with the early development and metamorphoses of invertebrates

Although his name stands in the first rank of investigators of these subjects, the most celebrated of his discoveries are those relating to the important part played by wandering mesoderm cells and white blood-corpuscles in the atrophy of larval organs, and in the defence of the organism against infection by bacteria and protozoa It was on these researches that he based his well-known "phagocyte theory" Metchnikoff's fundamental observations were made in Messina in 1882, and were published in the following year In these he showed that the absorption and disappearance of the embryonic organs of echinoderms were effected by wandering mesoderm cells, which devoured and digested the structures which had served their purpose and become effete The observation that white blood-cells accumulate in an inflamed area after infection by bacteria suggested that these cells might also devour and thus destroy the invading microbes, and that the process of inflammation was really a physiological and protective reaction of the organism against infection The study of the infection of Daphnia by *Monospora bicuspidata* entirely justified this prediction The account of the phenomena of infection as seen in this transparent crustacean was published in Virchow's *Archiv* (vol xcvi) in 1884, while, later in the same year, Metchnikoff published another paper extending these observations to vertebrates, and showing the universal applicability of his generalisation as to the essential character of the inflammatory process

During the twenty years which have elapsed since the publication of the "phagocyte theory," Metchnikoff, with the assistance of a host of pupils and disciples from all parts of the world, has been continuously engaged in the study of the reaction of the organism against infection, and in investigating the essential features of immunity in the light of the illuminating generalisation laid down in 1884

Though of limited range, and therefore inferior in scientific importance to the more fundamental researches carried out by him previously, Metchnikoff's recent work on infection by the microorganism of syphilis and the attainment of protection and immunity against this disease may be mentioned on account of its important practical applications

It is not too much to say that the work of Metchnikoff has furnished the most fertile conception in modern pathology, and has determined the whole direction of this science during the last two decades

Rumford Medal

The Rumford medal is awarded to Prof Hugh Longbourne Callendar, F R S, for his experimental work on heat

Prof Callendar has devoted his attention chiefly to the improvement of accurate measurement in the science of heat by the application of electrical methods His first paper, "On the Practical Measurement of Temperature," Phil Trans, 1887, paved the way for the application of the electrical resistance thermometer to scientific investigation In a later paper, written in conjunction with

Griffiths, "On the Boiling Point of Sulphur, &c," Phil Trans., 1891, the application of his method was further extended, and a simple method of standardisation was proposed. In continuation of this work Prof. Callendar has written a number of subsidiary papers dealing with details of construction of instruments, and applications to special purposes The results of this thermometric work have since been confirmed by Chappuis and Harker, Phil Trans, 1889, at the Bureau International, Paris, and by other observers, and are now generally accepted

More recent developments in accurate electrical thermometry have been described by Prof Callendar in later papers. He has also devised a special type of "gas-resistance" thermometer, depending on the increase of viscosity of a gas with temperature, which is the exact analogue of the electrical resistance thermometer, and possesses peculiar advantages for high temperature measurements.

The application of electrical resistance thermometers and thermo-couples to the observation of rapid variations of temperature has been utilised by Prof Callendar in the study of the adiabatic expansion of gases and vapours, and in the observations of the cyclical changes of temperature of the steam and of the cylinder walls in a steam-engine. The latter research was undertaken in conjunction with Prof Nicholson, with a view to elucidate the theory of cylinder-condensation

The researches of Rowland and other experimentalists on the specific heat of water and the mechanical equivalent of heat had shown that grave uncertainties affected the value of this most fundamental physical constant, which could not be removed satisfactorily without a complete investigation of the variation of the specific heat of water between 0° C and 100° C Prof Callendar devised a continuous electrical method of attacking this problem, possessing many important advantages as compared with older methods He was assisted by Dr Barnes in carrying out this work, the results of which form the subject of papers by Callendar and Barnes in the Phil Trans Roy Soc, 1901 As an illustration of the probable accuracy of their results it may be observed that, whereas by any of the older formulæ accepted for the variation of the specific heat of water, the values of Rowland and of Reynolds and Moorby for the mechanical equivalent are seriously discordant, they are brought into perfect agreement by the work of Callendar and Barnes

In the subject of conduction of heat Prof Callendar has contributed many original methods described in various minor papers, and, in addition to the thermal investigations with which his name is chiefly associated, has carried out some purely electrical researches

Royal Medals

One of the Royal medals has been awarded, with the approval of His Majesty, to Prof Alfred George Greenhill a fellow of the society on account of the number and importance of his mathematical investigations produced between the year 1876 and the present time They embrace a variety of mechanical and physical subjects, including dynamics, hydromechanics electricity, and gunnery He is the author of two treatises on hydromechanics, both remarkable for originality of treatment

The subject, however to which he has devoted most time and attention is the theory of elliptic functions His work on this subject may be placed in two classes —(1) Investigations in which he has extended the subject into new fields, as in the series of memoirs on the "Transformation and Complex Multiplication of Elliptic Functions," contributed to the Proceedings of the London Mathematical Society (vols xix xxi xxv, xxvii), and in the memoir on the "Third Elliptic Integral and the Ellipsotomic Problem," in the Phil Trans (vol cciii) (2) Applications to mechanical problems mainly dynamical, for purposes of calculation or illustration In this class may be placed his treatise on the elliptic functions as well as numerous papers in journals and the proceedings of scientific societies

All Prof Greenhill's work is characterised by much originality, and by a rare power and skill in algebraic analysis

His Majesty has also approved the award of a Royal medal to Dr Dukinfield Henry Scott, also a fellow of the society, for his investigations and discoveries in connection with the structure and relationship of fossil plants Dr Scott began the very important work which he has accomplished in this subject by helping the late distinguished palæobotanist, Prof W C Williamson In this cooperation he greatly enhanced the value of Williamson's work He not only added many new discoveries, but, what was more important, demonstrated the value of the work in relation to phylogeny

Dr Scott has since added much of first-rate importance He has discovered and elucidated many important types, his work constituting a most valuable acquisition to botany from the evolutionary point of view It is not only in the accurate investigation of difficult structures that Dr Scott has been so successful, not the least of his merits lies in the philosophical treatment of the problems suggested by his discoveries His position as one of the leading palæobotanists in the world is well recognised He has, both by his personality and by his writings, exercised a well-marked and widespread influence on the work of other botanists The fact that he has created in this country a vigorous school of palæobotanists may be regarded as an additional claim for the honour now conferred upon him

Davy Medal

The Davy medal is given to Prof Rudolf Fittig, professor of chemistry in the University of Strassburg, who began to publish scientific work as early as 1858, and in 1864 discovered the method for the synthesis of hydrocarbons homologous with benzene, which has ever since borne his name Up to about 1880 he worked chiefly on benzene derivatives, but his attention was gradually attracted to the study of lactones and acids, both saturated and unsaturated, which has largely formed the subject of his numerous published papers down to the present day

Fittig has been a remarkably active worker The Royal Society Catalogue contains under his name alone ninety-six papers, and, jointly with students and others, seventy-one more down to 1883 Since that time a number about equally large has been recorded in the indexes of the chemical journals The work of Fittig and his students on lactones and acids and particularly the intermolecular changes which many unsaturated acids undergo, may be said to be classical, and it has had an important influence on the progress of theoretical chemistry

Darwin Medal

The Darwin medal has been awarded to Prof Hugo de Vries, For Mem R S Prof de Vries has made a series of important discoveries in connection with the manner in which new races of organisms may originate, and he has materially extended and systematised our knowledge of the laws affecting the results of hybridisation His work is the outcome of very extensive experiments that have been carried on for many years He has stimulated numerous investigators, both in Europe and in America, to extend these inquiries, and the results already obtained are of great importance, both from a theoretical and from a practical point of view De Vries's work has exercised considerable influence on other branches of biology, and has suggested new lines of investigation in many directions

Hughes Medal

Mrs W E Ayrton is the recipient of the Hughes medal, which is awarded for original discovery in physical sciences, particularly electricity and magnetism, or their applications Her work on the electric arc has been described in a paper published in the Philosophical Transactions, and in various other publications

Mrs Ayrton's investigations cover a wide area She discovered the laws connecting the potential difference between the carbons of an arc with the current and with the distance between them, and proved these to apply, not only to her own experimental results, but to all the published results of previous observers Dealing with the modifications introduced into the arc by the use of cores in the carbons, she found the causes of these modifications The peculiar distribution of potential through the arc was traced, and its laws were discovered by her

Having found the conditions necessary for maintaining a steady arc, and for using the power supplied to it most efficiently, she was able to explain the cause of "hissing," and the causes of certain anomalies in the lighting power of the arc.

For the past four years Mrs. Ayrton has been engaged in investigating the causes of the formation of sand ripples on the seashore.

At the annual dinner, the Norwegian Minister, Dr. F. Nansen, proposed the toast of the Royal Society, and Sir William Huggins responded to it. Speeches were also made by Prof. Hugo de Vries, Prof. Callendar, Lord Kelvin, and the Italian Ambassador. In the course of his remarks Dr. Nansen said:—

Ibsen, my great compatriot, has in one of his works formulated the paradox that the man is strongest who stands most alone. There is certainly some truth in this—nay, there is much truth in it so far as science is concerned. The man who, in the search for truth, goes his own way independently of other men and of other considerations, is certainly the man who is apt to find the greatest and most valuable truth. On the other hand, it is also true that science, more than most other things in life, depends on cooperation, on the help of one's fellow-beings, and this becomes more and more true every day. Many people are apt to forget what science actually is, and what they owe to science, for it is through science that modern society actually exists, and the development of society as it is to-day would be impossible if science were eliminated. Humanity is growing, but if science and the means created by science are not growing humanity certainly will have to look forward to a very miserable future. Therefore the nation that wishes to be cared for must support science and those who carry on scientific work. Science will live her own life, and has done so ever since the days when Prometheus made his fatal expedition to the gods and stole the fire which is more or less burning in every one of us, and cannot be extinguished. There is something sublime in this everlasting fire of science. Generation after generation disappear, the individual is nothing, but always "Watchful in the tower man shall remain in sleepless contemplation."

NOTES

WE regret to have to record the death of Sir Edward J. Reed, K.C.B., F.R.S., on November 30, at seventy-six years of age.

IT is announced that this year's Nobel prize for chemistry has been awarded to Prof. H. Moissan, and the prize for physics to Prof. J. J. Thomson, F.R.S. The prize for medicine has been awarded to Prof. C. Golgi, of Pavia, and Prof. Ramón y Cajal, of Madrid.

THE Physical Society will hold an exhibition of electrical, optical, and other physical apparatus at the Royal College of Science, South Kensington, on Friday evening, December 14. Admission will be by ticket only.

IT is announced that Prof. Gariel has resigned the secretaryship of the council of the French Association for the Advancement of Sciences after having performed the duties for about thirty years.

IT is reported from Bombay that experiments in wireless telegraphy carried out between Landi Kotal and Peshawar have demonstrated the fact that the interposition of higher mountains does not interfere with free communication between two places in a mountainous country.

A JOINT committee has been formed of the county councils of the East and West Ridings of Yorkshire and the county boroughs of Bradford, Hull, Leeds, Rotherham, and Sheffield, to carry out an investigation as to the conditions of the milk supply of the district. The investigation is to be continued for twelve months, and the committee will shortly appoint a bacteriologist to make the necessary examination of samples of milk taken at various stages of transit to the consumer.

THE annual meeting of the German Society of Naval Architects was held in Berlin on November 22 in the presence of the German Emperor. A paper was read by Mr. Boveri on the Parsons marine turbine, in which he gave an account of steam-turbine trials in the German Navy. In the discussion that ensued it was urged that steam turbines possess various disadvantages. They render a ship less easy to steer and control; they are more complicated than ordinary engines, and, above all, they are 60 per cent. to 80 per cent. more costly. Notwithstanding these considerations, the large cruiser which is to be laid down next year will be fitted with steam turbines.

No work in medicine is of much use unless it is in living union with the study of the natural history of disease. This was the position taken by Sir Thomas Barlow in the course of some remarks made in opening, on November 28, a new Manchester and Salford Hospital for Skin Diseases. It is only when this purpose is kept in view that any solid advance can be made; it is only by trying to find out the causes and conditions under which diseases come, and by investigating their natural evolution, that real advance can be secured. In devoting a room to study and research, and in fitting it up with modern appliances, the committee of the new hospital has done something to stamp out quackery. In connection with skin disease, English people are very benevolent, but they have not yet learnt, as the people across the Atlantic have learnt, to give money for research; they give plenty of money for asylums and for hospitals, but for research which carries on the study of disease and advances knowledge on sound and progressive lines, that is one of the things which they, practical people as they are, have not yet realised.

THE following are among the lecture arrangements at the Royal Institution before Easter:—Mr. W. Duddell, a Christmas course of six experimentally illustrated lectures on "Signalling to a Distance, from Primitive Man to Radiotelegraphy," adapted to a juvenile auditory; Prof. Percy Gardner, two lectures on the sculpture of Aegina in relation to recent discovery; Prof. A. C. Seward, two lectures on survivals from the past in the plant world; Prof. W. Stirling, six lectures on the visual apparatus of man and animals; Dr. W. N. Shaw, two lectures on recent advances in the exploration of the atmosphere; Major P. A. MacMahon, two lectures on the standards of weights and measures; Prof. W. W. Watts, two lectures on (1) the building of Britain, (2) recent light on ancient physiographies; Dr. C. W. Saleeby, two lectures on biology and progress; and Prof. J. J. Thomson, six lectures on Röntgen, kathode, and positive rays. The Friday evening meetings will commence on January 18, when Sir Andrew Noble will deliver a discourse on fifty years of explosives. Succeeding discourses will probably be given by Sir Almroth E. Wright, Mr. J. J. Lister, Mr. Dugald Clerk, Prof. D. J. Hamilton, Prof. J. J. Thomson, and Prof. G. Lunge.

AT a recent meeting of the Royal Photographic Society Mr. Thomas Manly described and illustrated his modification of carbon printing, "ozobrome," which is rapidly gaining appreciation. The chief advantage of the new method is that carbon prints can be made without any exposure to light if a "bromide" print of the subject is available. The reduction of the bichromate in the carbon

tissue is effected by the silver image of the print It is only necessary to soak the hardened bromide print in water and the prepared carbon tissue or "plaster" in a solution that contains a bichromate, a ferricyanide, and a bromide, to squeegee the two together, and leave them for a short time under slight pressure The pigment plaster is then separated and treated exactly as if it had been exposed to light under a negative The silver of the bromide print has been converted by the process into a salt, but by treating it with a developing solution it is reduced to the metal again, and by this round of operations it will furnish "ozobrome" prints until it becomes destroyed by the handling. Mr Manly indicated a collateral advantage of the method in that it is independent of the colour of the pigment in the "plaster," while by the usual method of exposure to light the effect of the exposure penetrates more deeply in the presence of a blue than of a red or brown pigment

By the death of Emil Schmidt in his seventieth year a typical German anthropologist passes away Like many of his fellows he studied medicine, and was actually in practice for some twenty years He first directed his attention to American archæology, and dealt in particular with the Copper age His anatomical knowledge led him to take up physical anthropology, and he possessed a considerable collection of skulls, now in the Anatomical Institute at Leipzig, where he was for a time a recognised lecturer, and later extraordinary professor He was among the first to study the human remains at Pompeii, and a stay in Egypt enabled him to make a further study of early historic material Some years later he visited India and Ceylon, the whole of the material which he then collected was not published, but his "Reise in Sued-Indien" and "Ceylon" contain much valuable information In the much discussed problem of the Neanderthal skull he accepted in opposition to Virchow, the view that it is really that of a lower human species or genus, in the question of prehistoric pigmy races, on the other hand, he held that more evidence was needed as a basis for Kollmann's speculations In consequence of failing health he resigned his professorship in 1900, and occasional contributions from his pen appeared in *Globus* and other papers, but he knew that his life's work was done, and was seldom seen in scientific circles

We have received from the author, Mr J A Kershaw, of the Melbourne Museum a copy of a paper on additions to the fish-fauna of Victoria, published in the *Victorian Naturalist* for October Not any of the species are new

The record of fourteen years continuous breeding of the marsh-warbler in an Oxfordshire parish forms the opening article of the November *Zoologist*, the present year being the first since 1892 in which Mr W W Fowler has been unable to discover a nest of the species Ornithological notes made in Oxfordshire in 1904 form the subject of an article by Mr O V Aplin, while Mr E Selous discourses on sexual selection in the ruff

The slow-lorisis (Nycticebus) of the Indo-Malay countries, all of which have hitherto been generally regarded as members of a single variable species, are divisible, according to Mr M W Lyon (Proc U S Nat Mus, No. 1494), into two distinct groups, in one of which a distinct sagittal crest is developed on the skull of the adult, while in the other no such ridge occurs The second group occurs only in Borneo and Banka, and appears to be further characterised by having only one (in place of two) pair of upper incisor teeth

Copies are to hand of the second part for 1905, and of the first part for 1906, of the *Verhandlungen des naturhistorischen Vereins* of Prussian Rhineland, Westphalia, &c, published at Bonn The contents of the former include articles on a peculiar rock, essexit (heptorite), from Siebengebirge, on a portion of the Mayence Tertiary basin, on the ostracods of the Brunswick district, on the extinction of *Planaria alpina* in certain districts, and on some rare or exterminated plants of Rhineland The issue for 1906 is occupied by the first portion of a synopsis of the birds of the Rhine Province, by Dr Otto le Roi, of Bonn

We have received Heft ii and iii of the "Meeresfauna von Bergen" edited by Dr A Appellöf (Bergens Museum, 1906, pp 75–233, four plates, and three maps) In the first memoir Mr O Nordgaard reports on the Bryozoa of the west coast of Norway, in the second memoir Dr Appellof discusses the decapod crustaceans of the same region, with particular reference to their vertical and horizontal distribution It is shown that conditions of temperature and salinity are of fundamental importance in determining the distribution, though other factors, such as pressure nature of the bottom illumination, and chemical composition of the water are also operative

The origin of species, more especially in connection with variation and Mendelism, forms the leading feature of the issue of *Verhandlungen der Schweiz Naturfor Gesellschaft* for the present year The articles on this subject relate to the evolution of species generally, Mendelism as exemplified by hybridising garden and other snails, variation in butterflies, mutation in the harts-tongue fern, and species formation among bacteria and parasitic funguses In the case of the garden snail (*Helix hortensis*) Dr Arnold Lang shows that by crossing members of uniformly yellow shelled colonies with the fully-banded strain it will be found that the progeny follows to a great extent the Mendelian law in regard to the numerical proportions of the various colour-phases The issue concludes with a number of biographies of scientific men, accompanied by portraits

The most generally interesting article in the October number of the *Emu* is one by C I Barrett of Melbourne, on the origin of parasitic habits in cuckoos It is stated that one American species (*Coccyzus americanus*), which is generally in the habit of building a nest and hatching its own eggs, occasionally lays in the nests of other birds Another instance of the commencement of the parasitic habit is afforded by the Indian hawk-cuckoos of the genus Hierococcyx, five species of which lay in the nests of babbling thrushes while the sixth is reported to make a nest of its own In reference to the frequent resemblance between the eggs of cuckoos and those of the birds on which they are parasitic, the author cites a theory that the food of nestlings has much to do with determining the colour of the eggs which they may subsequently lay "If such be the case" he observes, "it goes far to explain the similarity between the eggs of many species of cuckoos and those of their foster-parents" The argument is, however, scarcely carried far enough for it is obvious that, if true, the explanation will likewise apply to "hedgesparrow-cuckoos" and "wagtail cuckoos" in the case of the European species

A FEW days' stay at the island of Ascension when the Scottish National Antarctic Expedition was returning home provided an opportunity for exploration Mr R. N R Brown furnishes an account of his botanical observations and collections to the second part of vol xxiii of the Transactions and Proceedings of the Botanical Society of Edinburgh Of the four phanerogams regarded as indigenous, only *Portulaca oleracea* and *Euphorbia origanoides* were found, but of the cryptogams collected four provided new records for the island

A NEW Russian botanical journal, representing the botanical section of the Imperial Society of Naturalists of St Petersburg, has been inaugurated under the editorship of Mr B Fedtschenko The first number contains a description, by Mr W Sukatscheff, of a new variety of *Pinus Pityusa* from the Crimea, and an ecological account of the flora of the province of the Don Cossacks is contributed by Mr W Droboff A feature of some interest in the latter is the occurrence of *Utricularia minor, Sparganium minimum, Eriophorum latifolium*, and other northern types

SEVERAL contributions concerned with the determination of Philippine plants are published as a fourth supplement to the first volume of the *Philippine Journal of Science* The list of new asclepiads determined by Dr R Schlechter includes species of Tylophora, Dischidia, and Hoya, and the same writer describes an endemic Burmannia allied to *Burmannia nepalensis* The Acanthaceæ were identified by Mr C B Clarke, and the Myrsinaceæ by Prof C Mez Among the second series of grasses named by Prof E Hackel are a curious Chionachne and a species of Ischæmum A second list of ferns contributed by Dr E B Copeland contains, among others, new species of Schizoloma, Athyrium, and Polypodium, and a collated list of Philippine fungi, prepared by Mr P L Ricker, is also published

IN the Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol l, part i) there is an able article on the development and present status of the steam turbine in land and marine work by Mr E M Speakman The author gives some valuable general considerations affecting their adoption, and incidentally points out that while the solution of the gas-turbine problem does not seem entirely impossible, little or no direct development can be expected until numerous difficulties of a practical nature have been overcome

A THIRD report on the geological features and mineral resources of the Pilbara goldfield, by Mr A Gibb Maitland, has been issued as Bulletin No 23 of the Geological Survey of Western Australia It covers ninety-two pages, and is accompanied by seven geological maps and thirteen illustrations It completes the descriptions of those mining centres in the goldfield to which no reference was made in the previous two Bulletins, and includes full details of the gold-mining districts of Tambourah, Western Shaw, Northern Shaw, and Just-in-Time, as well as of the tin-fields of Wodgina and Cooglegong It contains, in addition, an able summary of the mineral resources and future prospects of the whole goldfield If prospecting operations are carried on with due regard to the geological conditions, there can be no doubt that the district will continue to be a gold, tin, and tantalite producer The various tantalates and niobates of the rare earths, which exhibit marked radio-active properties, have been found to occur as primary constituents of the pegmatites such as are found at Wodgina It is probable, therefore, that careful search may result in the discovery of various radio-active minerals As minerals of subordinate importance, diamonds, scheelite, asbestos, and argentiferous lead ores are met with. Iron ores occur plentifully throughout the district, but at present such ores, though of high grade, are entirely beyond the reach of commercial enterprise.

VOL xxxvii of the *Sitzungsberichte* of the Physico-medical Society of Erlangen for the year 1905 shows a very marked increase in the activity of the society as compared with previous years The following papers may be noticed as possessing special interest —a detailed investigation of electric discharges, by Mr R Reiger (pp 1–130), a series of papers by Prof E Wiedemann dealing with the history of science, and referring in particular to the early scientific knowledge of the Arabs, details of the determination of the atomic weight of tellurium by Mr A Gutbier, and of bismuth by Mr H Mehler, and a paper on radio-tellurium by Mr F Henrich

SINCE the first X-ray tube was constructed by Prof Rontgen, many modifications have been introduced of greatly increased efficiency The most recent improvements have been directed to the purpose of making the vacuum adjustable, so as to be able to convert, for instance, a tube which has become very "hard" into a tube of a "softer" character Mr Rosenthal, of Munich, describes in the *Verhandlungen* of the Berlin Röntgen Congress, 1906, a new type of tube, in which, it is contended, the character of the vacuum does not undergo variation at all after prolonged working The principle consists in absorbing all those rays which emanate from the anti-kathode and are not true Röntgen rays, by an internal aluminium 'filter", these rays do not, therefore, strike the glass walls of the tube or produce the customary heating and chemical effects which cause the vacuum to change It is claimed that the new device is a really substantial improvement, both as regards convenience and economy

AN interesting study of the question whether an enzyme is capable of possessing more than one kind of activity is contained in a paper by Messrs L Marino and G. Fiorentino published in the *Gazzetta* (vol xxxvi, ii, p 395) It is contended that the maltase of malt, free from emulsin and invertase, is capable, not only of decomposing maltose but also of hydrolysing the natural and artificial glucosides which are susceptible to the action of emulsin The absence of the latter in the maltase is held to be proved by the fact that the enzyme recovered after the action of maltase on amygdalin has taken place is almost without effect on salicin, whereas if a trace of emulsin is added to the maltase the enzyme recovered under similar conditions almost completely hydrolyses salicin The activity of maltase appears, indeed, to be destroyed by the products of the hydrolysis of amygdalin, whilst the latter do not affect emulsin The maltase of malt seems to be very similar to the maltase of beer yeast, as it is capable, like the latter, of producing the same isomaltose synthetically from glucose, but it differs from it in hydrolysing the β, not the α-glucosides.

THE formation of hydrocyanic acid in plants, which was first investigated in the case of bitter almonds by Liebig and Wöhler in 1837, has recently attracted attention owing to the discovery by Prof Dunstan and Dr Henry in certain fodder plants, known to cause cattle poisoning, of definite

glucosides susceptible of decomposition by specific enzymes with the production of the highly-poisonous prussic acid In a communication to the Royal Academy of Belgium (Bulletin No. 8, p 613) M P Fitschy adds another half-dozen common plants to the number of those already known to produce prussic acid in the early stages of their growth Among the Ranunculaceæ are *R repens* and *R arvensis*, and among the grasses *Gynerium argenteum*, *Melica altissima*, *M nutans*, *M uniflora*, and *M ciliata* It remains to be ascertained whether the prussic acid is originally elaborated in each plant in the form of a definite glucoside, and whether a specific enzyme is responsible for its decomposition

A NEW edition of Mr Sidney Lupton's "Numerical Tables and Constants in Elementary Science" has been published by Messrs Macmillan and Co, Ltd. The present issue is substantially similar to the last edition, but a few values have been corrected, and an addendum of two pages contains important values and constants recently obtained

A SUPPLEMENT to the report of the Rugby School Natural History Society for the year 1905 has been published It contains a paper by Mr G L Keynes on a late Roman settlement near Somersham, Hunts, and is illustrated with photographs and drawings of the objects found during the excavation of the settlement

MESSRS BRADY AND MARTIN, LTD, of Newcastle-upon-Tyne, have issued the seventh edition of their well-arranged catalogue (pp 700) of scientific apparatus This enterprising firm is prepared to supply instruments and material for the practical study of all branches of science, and teachers will do well to examine the volume when selecting apparatus or accessories for lecture-room or laboratory

THE use of models for the teaching of solid geometry forms the subject of two articles by M Charles Playoust in *Cosmos* for September 8 and 15, the object being to show how easily models can be constructed out of cardboard or with strings by a teacher or student, in cases where the cost of a set of proper models would be prohibitive

AN English version of Prof H Poincaré's articles on "The Value of Science" is appearing month by month in the *Popular Science Monthly* The November article deals with "The Notion of Space" A German translation of the same book by Prof and Frau Weber, of Strassburg, has been published by Teubner, of Leipzig

OUR ASTRONOMICAL COLUMN

DISCOVERY OF A NOVA —Circular No 121 of the Harvard College Observatory contains an account of the discovery, by Miss Leavitt, of a new star in the constellation Vela This object was discovered on a plate taken with the 1-inch Cooke lens on December 5, 1905, and also on fourteen plates taken between that date and June 29, 1906 Its position, for 1900, is

$$\text{R A} = 10\text{h } 58\text{m } 20\text{s}, \text{ dec} = -53^\circ\ 50'\ 9$$

On a plate taken on July 12, 1905, showing stars down to magnitude 11 5, Nova Velorum is not to be found, nor did it appear on the 127 plates of this region taken between 1889 and December, 1905, all of which have been examined and found to show stars down to the eleventh magnitude

So far as can be determined from the Harvard plates, the greatest magnitude attained by this Nova was 9 72, the magnitude on December 5, 1905, and January 26, 1906 There were considerable fluctuations of light during the period covered by the observations, and Prof Pickering thinks there is little doubt that the object observed is actually a Nova

COMETS 1906*g* AND 1906*h* —Observations of these two comets are recorded in Nos 4135–6 of the *Astronomische Nachrichten* Observing at Arcetri, Prof Abetti saw comet 1906*g* as a round, uniform nebulosity of 2′ diameter, in which neither nucleus nor any trace of a tail could be discerned Prof Ambronn, at Gottingen, found a feeble condensation, but no nucleus, on November 19 According to Prof Nijland, the magnitude, as estimated from an opera-glass observation on November 19, was 7 7

A set of elements computed by Herr M Ebell for comet 1906*h*, and published in Circular No 94 from the Kiel Centralstelle, shows that this body passed through perihelion on September 15 The Circular also gives an ephemeris from November 26 to December 16, which shows that the comet's brightness is decreasing

OBSERVATIONS OF NOVA SAGITTARII —Since May 10, 1899, Prof Barnard has observed Nova Sagittarii on many occasions with the 40-inch refractor at Yerkes, and now publishes the results in No 4136 of the *Astronomische Nachrichten* This Nova was discovered from the Harvard photographs, of which one, taken on March 8, 1898, showed it to be of magnitude 4 7 Prof Barnard's observations gave the following magnitudes for the mean dates of the years named —1899, mag 11 0, 1903, mag 13 8, 1906 mag 14 8 From these it appears that the Nova may fade entirely from view in the next few years The published positions of this star seem rather discordant, so Prof Barnard has investigated the matter, and gives data which will prevent the position of the Nova from being mistaken The appearance of the Nova in the 40-inch telescope is that of a very small nebula, or hazy star, about 1″ in diameter Extending the focus about one-quarter of an inch seemed to improve the definition, but still left the image of the Nova hazy, something like the abnormal stars in the cluster M13 Herculis

TWO STARS WITH VARIABLE RADIAL VELOCITIES —From spectrograms taken at the Potsdam Observatory, Prof Hartmann has discovered that the two stars RZ Cassiopeiæ (an Algol variable provisionally designated 77 1906 Cassiopeiæ) and γ Cassiopeiæ have variable radial velocities In the former case the spectrograms show a variation between +33 1 km (October 1, 1906) and −11 9 km (October 4, 1906), the first value obtaining about one-quarter of the star's period before, and the second about the same length of time after the minimum The measures of the spectrograms of γ Cassiopeiæ gave values between +3 1 km (September 21, 1900) and −19 3 km (September 27, 1901) Owing to the hazy character of the lines in the spectrum of this star, the resulting velocities are somewhat uncertain (*Astronomische Nachrichten* No 4135)

GRAPHITIC IRON IN A METEORITE —In an extract (No 1497) from the Proceedings of the U S National Museum Mr W Tassin describes the physical and chemical properties of a nodule of graphitic iron found in the Canyon Diablo meteorite The mass was found on examination to be a septarian nodule, the septa consisting of native metals similar to the mass of iron The interseptal portions consist of crystalline graphitic and amorphous carbon, mixed with a very fine granular or scaly troilite There is also present a lustrous metallic substance differing from cohenite in that it is soft enough to leave a mark on white paper, is dark steel-grey in colour, and occurs in angular, foliated masses Chemical analysis showed that this material contained iron (88·8 per cent), nickel (4 0 per cent), silicon (2·0 per cent), carbon (4 3 per cent) phosphorus (0 9 per cent), and a trace of cobalt

NEW VARIABLE STARS —In No 4126 of the *Astronomische Nachrichten* Prof Max Wolf announces the discovery of thirty-one new variable stars in the region about β Cygni The variability of these objects was discovered from plates taken with the Bruce telescope with exposures ranging from 150 to 220 minutes A number of separate charts show the positions of these stars

RECENT PROGRESS IN MAGNETO-OPTICS [1]

It is my intention this evening to give you a general review of the experimental researches which have occupied me during the last few years They all refer to the relation between magnetism and light, a relation the first and fundamental example of which was discovered in this very institution by Faraday in 1845

Surely every physicist should feel inspired by the idea of having the privilege to address an audience in the same lecture room, where so often some of nature's deeper mysteries were revealed, and I feel the uplifting force of this inspiration all the stronger, as my own work for many years has been so closely connected with one of Faraday's discoveries Faraday discovered that the plane in which the vibrations of light take place *rotates* whenever a ray of light is propagated parallel to the magnetic lines of force through some substances, such as Faraday's own heavy glass, this fact we now indicate by the term *the magnetic rotation of the plane of polarisation* The discovery of this fact opened the chapter of magneto-optics

Faraday's mind again and again returned to the relation between magnetism and light, and incessantly he sought for closer and more intimate connections, in one experiment in March, 1862 (which is said to have been his last), he tried to observe a change in the spectrum of a flame when acted on by a magnet The entry in Faraday's note-book, preserved in this institution with pious care, concludes with the words, "not the slightest effect on the polarised or unpolarised ray was observed" As we now know, the means of Faraday's time were not powerful enough to observe the effect sought for Various physicists since Faraday have sought in the same direction, some have recorded their negative results, others have not, for most physicists have an almost invincible dislike for the publication of negative results, though a collection of such unsuccessful attempts, if precisely stated, would be most interesting, and should afterwards prove very valuable

Magnetisation of the Spectral Lines

In my own case, the thought to submit a source of light to the influence of magnetism occurred to me during a quantitative investigation of the effect discovered by Kerr concerning the light reflected by magnetised mirrors I was working at the time in Leyden, in Prof Onnes's laboratory The account of Faraday's negative experiment encouraged me in my endeavours, and also an argument in 1856 by Lord Kelvin referred to by Maxwell as the "exceedingly important remark of Sir W Thomson" If it might be accepted that the forces operating during the propagation of light in magnetised substances exist also whenever the source of light is in the magnetic field, we can expect some direct effect of magnetism on radiation

My own successful experiments date from 1896 to 1897, whereas three years earlier I also had recorded a negative result not having then used adequate means

As you know, a sodium flame chiefly emits two kinds of yellow light and accordingly its spectrum, when analysed with one of Rowland's large concave gratings shows two yellow lines With a grating of medium size these lines have a distance of one millimetre they are rather narrow as shown in the slide In August, 1896, I found that when a sodium flame is placed between the poles of an electromagnet, and is looked at with a spectroscope in a direction at right angles to the lines of force, the yellow lines in its spectrum become somewhat wider when the magnetic field is put on [2] This fact can be expressed in a different way by saying that, besides the original vibrations, a flame in a magnetic field emits other vibrations, of which some have a somewhat greater, and some a somewhat smaller frequency than the original vibrations

This observation of a small change in a spectral line was the origin of my subsequent work I realised that this change however small, was worth a closer examination Indeed, it seemed clear at once that here we had a means of studying the internal vibrations of a molecule by modifying in a simple way the conditions under which they are going on Of course, the result was verified in all directions As there is now, I think, no doubt as to the reality of the observed changes, I shall only refer very briefly to this stage of the work. In the first place, the widening of the lines was observed in the direction of the lines of force also. Then the fact was established that to the observed *direct* effect there corresponds an *inverse* one. When white light traverses the incandescent sodium vapour we observe the absorption lines, these also are widened when the vapour is subjected to magnetic forces. Secondary influences were discarded by suitable modifications of the experiments In one case no change was observed The spectra of fluted bands, such as those of iodine, carbon, or nitrogen, did not show any effect, nor could Becquerel and Deslandres using increased power discover it

Before I could answer the different questions which presented themselves, I had the advantage that the beautiful theory of the electromagnetic and optical phenomena, developed by my friend Prof Lorentz, gave its quickening influence to my experimental work.

In this theory it is supposed that the material world is built up of three things, ponderable matter, ether, and *electrons* I think it is rather superfluous to remind you here in the land of Maxwell, Kelvin, Crookes, J J. Thomson, Schuster, Larmor, Heaviside, and Johnstone Stoney, that electrons or corpuscles are exceedingly small, electrically charged particles, which are supposed to be present in all material bodies

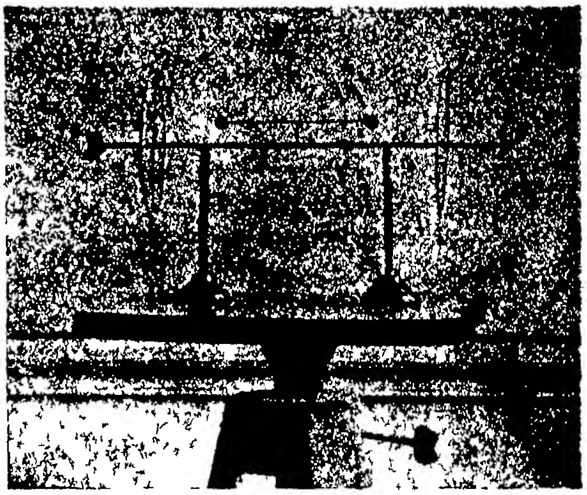

FIG 1

These electrons can perform oscillations under the influence of the forces which attract them to their position of equilibrium Because they are electrified they have sufficient hold on the ether to excite in it the electromagnetic vibrations which, according to Maxwell's theory, constitute light The oscillatory periods of the electrons determine the position of the lines in the spectrum, and with every change in the period of oscillation we observe a displacement of the corresponding line

In Lorentz's theory the explanation of the effect of a magnetic field is as simple as it is beautiful

The forces operating on the vibrating electron in a magnetic field are fairly well known These forces are the same which curve the path of the kathode rays in a vacuum tube which is acted on by a magnet All motions of the electrons in the molecules of a flame may be supposed to be made up of three particular motions, chosen in such a manner that the action of the magnetic field on each of them can be easily foreseen The light of the flame is exactly the same as it would be if the flame contained three groups of electrons vibrating in these simple ways In this model the electrons are represented by red balls, the black arrow indicates the direction of the magnetic force (Fig 1)

[1] Discourse delivered at the Royal Institution on Friday, March 30, by Prof P Zeeman

[2] Zeeman, Verslagen Kon Akademie v Wetenschappen, Amsterdam, October and November, 1896 *Phil Mag*, March, 1897

As a first simple motion we choose a vibration parallel to the lines of force. On the group of electrons which possess this motion the magnetic force has no influence, the period, which we call T, remains unmodified The other two simple motions are circular motions, clockwise or anti-clockwise, in planes perpendicular to the lines of force

An electron performing either of these rotations will be acted on by a force which is directed towards or from the centre, dependent on the direction of the rotation The magnetic field must, therefore, cause the speed of the electron either to increase or to decrease, and so will either diminish or increase the period Therefore, instead of one motion with period T, we get under the influence of the field three motions with periods T, $T+v$, $T-v$, v being a small quantity To each motion of the electrons there corresponds a luminous vibration, according to the electromagnetic theory of light Observing with a spectroscope we must, therefore, see each spectral line divided into three lines, each line becomes a *triplet*[1]

I will show you a few examples of lines which are really divided into three components in accordance with Lorentz's theory (Fig 2, iron, Fig 3 part of iron spectrum)[2] You will notice that each of the components remains very narrow, it is not a hazy effect, but a very definite one This certainly would not be the case if all molecules did not behave in the same manner, and if certain conditions of isotropy of the molecules were not fulfilled[3]

FIG 2

The consideration of the model may illustrate some other points which were foreseen by Lorentz's theory Consider the light emitted at a right angle to the lines of force The three kinds of light seen in this direction are each due to vibrations of one kind, and therefore polarised We can, therefore, extinguish the light of the central component or of the two external components of the triplet by a Nicol In one half of the slide shown the external components are extinguished, in the other half the central one So, for the first time we were now able to get polarised radiations from the molecules of a gas All attempts to produce such simple vibrations from gaseous molecules had hitherto failed

With some lines the central component and the outer ones differ much in intensity If this be the case the spectroscope can be dispensed with entirely, and we may observe a partial polarisation of the light emitted by the vapour in the field as found by Egoroff and Georgiewsky We shall now consider the light emitted in the direction of the lines of force (Fig 4)

It is seen at once that each line must split up into two components Moreover, both lines must be circularly polarised, but in opposite directions With suitable arrangements, in one half of the field of view the one in the other the second, component can now be extinguished I observed this circular polarisation for the first time in the case of the sodium lines now shown You see how complete the circular polarisation is There is no trace of rectilinear or of elliptic polarisation[4]

When I first looked for this circular polarisation, I did not have the field of view divided into two parts, but the position of the line was determined by means of a spider's thread On the reversal of the magnetising current the luminous line moved I do not wish to disguise the fact that no observation has ever afforded me so much pleasure as this one

It has already been remarked that we can also study the absorption lines which become visible when white

FIG

light is transmitted through the vapour We then study the inverse effect I shall use it to show you at least something directly depending upon the effect, because the effect itself is too young to appear before so large an audience The inverse effect for light parallel to the lines of force plays a part in an experiment due to Righi[1] Consider a horizontal ray parallel to the axis of an electromagnet with pierced poles, and let crossed Nicols be placed

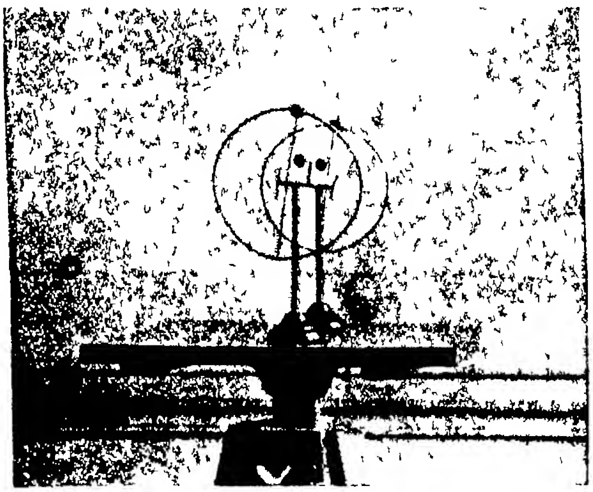

FIG 4

before and behind the instrument, as in Faraday's experiment A sodium flame in the field emitting two kinds of circularly polarised rays absorbs these same radiations but does not stop the radiations polarised in the opposite

[1] Zeeman, Verslagen Kon Akademie v Wetenschappen Amsterdam Mei, Juni, October, 1897 *Phil Mag* July and September, 1897

[2] The photographs illustrating this lecture are excepting the diagrams, enlarged copies from negatives. The scale is different in the various cases The separation of the outer components is of the order of one sixth of the distance of the sodium lines (the vertical lines in Fig 5) No 2 is a copy of one of the first photographs I obtained The author is indebted to Prof Runge for No 11 The ronet is not distinctly shown in the latter reproduction In the Proceedings of the Royal Institution some additional Figs will be reproduced

direction These remaining circularly polarised rays cannot be extinguished by a Nicol

The brilliant yellow spot which appears on the screen as soon as the current is put on is due to such rays The explanation of this experiment is not complete, however, at least not for denser vapours The Faraday rotation of the plane of polarisation then plays a part, as we shall see further on

The magnetisation of the spectral lines allows us to determine whether positive or negative electrons are vibrating in a flame From the phenomena in the direction of the lines of force, it follows that in a luminous gas *the negative* electrons give rise to all vibrations It does not follow, however, that the luminous molecules have a negative charge On the contrary, the researches of Lenard and Stark show that at least part of the luminous spectra is emitted by positively charged atoms

When a line is split up into a triplet, we can, by measuring the amount of the effect, find out how much matter is loaded with the revolving electron, or, in other words, we can determine the ratio of the charge e to the mass m of the electron In this manner I have made the *first determination of this notable number* e/m, *and* found it of the order of magnitude of 10^7 electromagnetic units per gram [1] The most accurate measurements of the present time for different spectral lines yield values ranging between 1 4 and 1 8 by 10^7 This number is about 1500 times the corresponding number for hydrogen as deduced from the phenomena of electrolysis

We must, then, conclude that at least a majority of spectral lines is due to the vibrations of the negative electron This conclusion is not only valid for incandescent sodium or mercury All elements which can give colour to a flame or which can be evaporated in a spark show the magnetisation of the spectral lines, and hence in all elements these negative electrons are present

Independent experimental evidence for the existence of electrons has been derived from the study of the kathode rays in a vacuum tube The discontinuous structure of electricity was also proved by other phenomena, and in this way physicists were led by purely experimental methods to the negatively charged corpuscle of J J Thomson, 1500 times smaller than the hydrogen atom, in full accordance with the electron necessitated for the explanation of the magnetisation of the spectral lines

All fundamental characteristics of the magnetic resolution of the spectral lines were then explained, and the truth of the explanation proved beyond the possibility of doubt More detailed knowledge of the effect has been greatly extended by a whole series of investigators, especially by Becquerel, Cornu, Cotton Michelson, Kent, Konig, Righi, Reese, Runge and Paschen, and in this country by Gray, Preston, Lodge, Lord Blythswood, and others, and from the theoretical side by Larmor, Fitzgerald, Jeans and J J Thomson

Not all spectral lines are tripled, some are split up into quartets, others into sextets The lines D_1 and D_2 in strong fields are an example The whole of such a system of lines is, even in the strongest fields, confined to the space of one-sixth of the distance of the sodium lines In some cases still more complicated subdivisions have been observed, especially by Michelson In such cases the simple electromagnetic model of a molecule emitting light is insufficient We shall return to this subject afterwards, and first proceed to a discussion of *phenomena accompanying the inverse effect*

This investigation, which I carried out in Amsterdam together with my pupils, Drs Hallo and Geest, was suggested by a theoretical investigation by Prof Voigt, of Gottingen Lorentz's theory relates to one single vibrating particle, and can only be applied to substances of very small density which emit very narrow spectral lines With greater density, and therefore broader spectral lines, the mutual influence of the molecules must be taken into account It seems, however, that a theory of emission of a system of reciprocally reacting molecules is rather difficult In the case of absorption the problem is easier, and is considered by Prof Voigt in his theory of magneto-optical phenomena [1] He does not deal with the electrons directly, but adds suitable new terms to the equations of motion in an absorbing medium. His method establishes a connection between the rotation of the plane of polarisation and the resolution of the spectral lines, a connection almost simultaneously pointed out by Fitzgerald. This also led to an interesting result, until then missed by the electronic theory, namely, rotation of the plane of polarisation close to an absorption band

(*To be continued*)

MINERAL RESOURCES OF THE UNITED STATES.

FROM time to time we have directed attention to the variety and magnitude of the work being carried on by the United States Geological Survey Of all the work undertaken, none is of greater value to the general public than that of the division of mining and mineral statistics under the able direction of Dr David T Day, whose masterly report (Washington, 1905) on the mineral resources of the United States for 1904 has recently been issued The volume covers 1264 closely printed pages, and in arrangement and scope is similar to the twenty preceding annual reports of the series Each chapter is a census of the productive features of the industry under discussion from the pens of statistical experts The figures dealt with are stupendous. In 1904, for the fifth time, the total value of the mineral production of the United States exceeded the sum of 200,000,000*l*, and it is curious to note that the value of non-metallic minerals exceeded that of metallic minerals by 41,000,000*l* Iron ore and coal are the most important of the mineral products Statistics of the production of moulding sand were collected for the first time in 1904. Another novelty is a report, written by Mr H H Hindshaw, directing attention to the occurrence of peat in the United States and to its possibilities as a source of fuel Appended to the report is a useful bibliography of the subject Tin ore was produced commercially, though in small quantities, in South Carolina South Dakota, and Alaska

There is a constant increase in the demand for such abrasives as corundum and emery, and consequently the publication of Bulletin No 269 (Washington, 1906), on corundum and its occurrence and distribution in the United States, by Mr J H Pratt, is a welcome addition to technical literature It is an enlarged edition of Bulletin No 180, published in 1901, and has grown from 98 pages to 175 pages It is admirably illustrated with eighteen plates, and constitutes a complete monograph on the three varieties, sapphire or gem corundum, corundum, and emery All the occurrences in the United States are described, and particulars are added regarding the distribution of corundum in other countries, the methods of mining and cleaning, and the uses of corundum In conclusion, some useful suggestions to prospectors for chromium are given

The most remarkable outcome of the recent work of the mining division is the extensive series of tests of the various coals found in the United States These are recorded in three bulky quarto volumes forming Professional Paper No 48 (Washington, 1906), and covering 1492 pages The work was carried out at the coal-testing plant of the United States Geological Survey at the St Louis Exhibition under the direction of a committee consisting of Messrs Edward W Parker, Joseph A Holmes, and Marius R Campbell The first volume describes the field work, classification of coals, and chemical work, the second deals with boiler tests, and the third with producer-gas, coking, briquetting, and washing tests The results are of far-reaching importance in the solution of the fuel and power problems upon which the varied industries of the United States depend Most of the American bituminous coals and lignites can, it was found, be used as a source of power in a gas-producing plant, the power efficiency of bituminous coals when thus used being two and a half times greater than

their efficiency when used in a steam-boiler plant Some of the lignites from undeveloped, but extensive, deposits in North Dakota and Texas showed unexpectedly high power-producing qualities, and it is shown that certain of the dry, non-coking, bituminous coals and semi-anthracites, which are now almost wasted, can be converted into useful fuel by briquetting The work of the chemical laboratory in connection with the sampling of the coal has undoubtedly set a standard for similar work in the future The total sum appropriated for the work by the United States Government was 12,000*l*

The United States Geological Survey has undertaken a far-reaching investigation of all the lead and zinc deposits in the Mississippi valley. A large part of this field has been investigated by the Wisconsin Geological Survey, and an interesting report on the ore deposits, with an atlas of eighteen detailed maps, has been published by Mr U S Grant (Bulletin No xiv, Madison, Wisconsin, 1906) The results brought out by these maps in regard to the relations and origin of the ore are extremely satisfactory, in that they show that a large portion of the ore deposits are confined to the structural basins

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge —The voting on the proposed new regulations for the mathematical tripos will take place at a Congregation to be held on Friday and Saturday, February 1 and 2, 1907.

The general board of studies has recommended (1) that a university lecturer in hygiene be appointed, in connection with the special board for medicine, with an annual stipend of 100*l* payable out of the funds in the hands of the State Medicine Syndicate, (2) that a university lecturer in pathology be appointed, in connection with the special board for medicine, with an annual stipend of 100*l* payable out of the common university fund

The general board of studies has approved Mr E W Barnes, Trinity College, for the degree of Doctor in Science

Prof M E Sadler will distribute the prizes at the Merchant Venturers' Technical College, Bristol, on Thursday, December 20

Lord Monkswell will distribute the prizes and certificates to students at the Borough Polytechnic Institute on Tuesday, December 11, at 8 p m

A gift having the annual value of 500*l* a year has been made to the University of Paris by Mr Andrew Carnegie for scholarships to be awarded for the purpose of carrying on research in the laboratory of Mme Curie

A statue of the late Principal Viriamu Jones, F R S, first principal of the University College of South Wales and Monmouthshire, and the first senior Vice-Chancellor of the University of Wales, was unveiled at Cardiff, on December 1, by Viscount Tredegar

A deputation from the executive of the Association of Education Committees was received by Mr Birrell at the Board of Education on November 29 The deputation sought to obtain more elasticity in the local development of higher education, greater freedom for local education authorities in the training of teachers, and increased Imperial aid for the relief of education rates Mr Birrell, in reply, expressed his sympathy with the ideals and most of the objects of the association, and his regret that the Treasury could not authorise him to promise at present any further grant of public funds in relief of local education rates

An unusually interesting and important Blue-book (Cd 3255) has just been issued by the Board of Education. It deals with statistics of public education in England and Wales for the years 1904–5–6 Every grade of school is dealt with, and it is now easy to trace the growth of educational enterprise in recent years One of the numerous sections is devoted to technical institutions, that is, as defined by the regulations of the Board, to institutions giving organised courses of instruction in day classes In 1904–5 twenty-three such institutions only were recognised, 2509 students attended them at some time during the year, grants amounting to 8542*l* were paid on 1295 students attending a full course of instruction, and 1507*l* on 489 students attending part only of a course Small as these numbers are, it is satisfactory to find they are larger than the corresponding figures for 1903–4 These students were taught by 416 teachers, of whom nine were women, numbers representing an increase of 108 in the teaching staff in the year The average age of the students attending these classes was rather low Of the total number of students, under 300 were women and girls, 1136 were between fifteen and eighteen years of age, 879 between eighteen and twenty-one, and 494 were more than twenty-one years of age Courses of work in engineering and in applied chemistry were most numerous During 1904–5 the number of evening schools recognised reached 5706 and the number of students who attended at any time during the year 718,562, a grant was paid on 487,699 of the total number of students The amount of the grant reached 320,762*l* Of this total number of students as many as 155,938 were under fifteen years of age, and 202,707 were more than twenty-one years Two-thirds of the students were men or boys This Blue-book will prove indispensable to educational administrators everywhere

The scholarships, medals, and prizes gained by candidates at the examinations of the London Chamber of Commerce were distributed on November 30 by Mr Asquith, Chancellor of the Exchequer, who subsequently delivered an address After referring to the growth of the educational work of the Chamber of Commerce, Mr Asquith said that men and women of all classes and schools of opinion must agree in feeling gratification that during the last twenty or thirty years we have by our continuation classes, by our technical classes, by our polytechnics, been endeavouring, at any rate, to superadd to the common basis of education which was the possession, or ought to be the possession, of all classes of the community, some means of equipping men and women for the special exigencies of the particular branches of their profession in life The English people, who have some very excellent qualities, have some ingrained and almost ineradicable superstitions All agree that in the case of what are called the learned professions some kind of special training and knowledge is needed before a man takes upon himself the pursuit of his calling in them, but every Englishman thinks he is perfectly qualified to take up without any preliminary training the work of business But Mr Asquith continued, we cannot now take things in the easy-going and the happy-go-lucky fashion that we used to do The strain of foreign competition presses upon us in every walk of business and every market in the world, and, whatever are the contributory causes of the pressure which we all in a greater or less degree experience there is not a man acquainted with the facts who will not agree that in the case, at any rate, of some of our most formidable competitors—for instance Germany and the United States—one of the great sources from which they have derived exceptional strength in their commercial and industrial struggle with us has been the superior development of their technical and educational system

SOCIETIES AND ACADEMIES

London

Royal Society, June 21 —"The Action of Radium and Certain other Salts on Gelatin" By W A Douglas **Rudge.** Communicated by Prof J J Thomson, F R S

The author has completed his experiments on the above subject, following the method first described in Nature (vol lxxii, p 631) A "growth" which appears cellular in structure is seen to occur when a radium salt is put in contact with gelatin This growth is traced to the formation of an insoluble precipitate of barium sulphate owing to the barium always associated with radium salts and the sulphuric acid usually present in commercial samples of gelatin Specially prepared gelatin containing no sulphuric acid gives no growth

A sample of gelatin from which the sulphuric acid had

been removed was sealed up with some radium salt in September last, and at the present time no signs of growth have made their appearance, but if to a portion of the gelatin a soluble sulphate is added a growth at once appears

A series of photographs has been taken by means of the large photomicrographic apparatus of Zeiss, using magnifying powers of from 400 to 4000 diameters

It thus seems to be quite clear that the cellular growth cannot be produced by radium or barium unless a sulphate is present, and other metals, save Sr and Pb, fail to produce any result, because they do not form insoluble sulphates

The cellular form of these precipitates is probably due to the circumstance that the gelatin is liquefied by the actions of the salt, and each particle of precipitate is formed about a core of gelatin, so that the layer of barium sulphate forms a kind of sac or cell which is surrounded by the solutions of the salt in the liquefied gelatin This *cell* may be permeable to the liquefied gelatin containing a salt in solution which, passing through the cell wall, causes an expansion to take place, the limit of growth being controlled by some surface-tension effect

The conclusions which are drawn from a study of the photographs and direct examination under the microscope with high powers are that —

(1) The cells form round a precipitate of an insoluble sulphate and the energy of the growth of the cell depends upon the amount of sulphate present

(2) *Radium has no specific action in forming cells* any effect produced being due to the barium associated with it, and the purer specimens of radium salts are less satisfactory as cell-formers than the impurer ones Probably pure radium salt would have no action except that of causing an evolution of gas

(3) The cells do not divide or bud, or show anything resembling "karyokinesis," their growth very quickly reaches a maximum, and they do not decay or split up, save as a consequence of the drying of the gelatin If the cover glass is sealed down with cement, the cells have been observed to suffer no alteration in the course of four months

(4) Radio-active substances, unless they contain barium, do not give rise to the formation of cells

November 1 — "The Anæsthetic and Lethal Quantity of Chloroform in the Blood" By Dr George A **Buckmaster** and J A **Gardner** Communicated by Dr A D Waller, F R S

The amount of chloroform present in the arterial blood of animals at various stages of anæsthesia has been accurately determined by the authors for the first time in this country All observers who have worked at the question of chloroform-anæsthesia, including those members of the Special Chloroform Committee of the British Medical Association who have specially investigated this point, are agreed that chloroform is tenaciously held by blood, and that the transport of the drug from alveolar air to the cells of the body and the nervous system is probably effected by the red corpuscles

The authors have given in some detail an account of the researches recently undertaken by French observers J Tissot and Mansion, and M Nicloux who have improved on the original methods employed by Gréhant and Pohl by using the reaction described by Dumas in 1821 To ascertain the amount of chloroform in blood, this is distilled off from the liquid, boiled with alcoholic potash, and the potassium chlorate thus obtained is titrated with silver nitrate

In the experiments now described, the amount of chloroform in arterial blood at the moment when both the conjunctival and tail reflexes have disappeared, when the respiratory movements cease, and when the reflexes reappear, has been calculated from the difference in the chlorine-content of the blood before and after the administration of the anæsthesia The method of estimation was the well-known one introduced by Carius for determining the amount of halogen in organic compounds and by the adoption of Gooch's method of filtration and J P Cooke's suggestion of washing the silver chloride precipitate with water containing a little silver nitrate, a very high degree of accuracy was obtained. For the validity of this method the natural chlorine-content of the blood must be shown to remain constant during the course of any single set of experiments Several tables show that this is the case during prolonged anæsthetisation with ether, the actual deviations from the mean being only 0·00123 and 0·00165.

The majority of the observations have been made on cats, since the phenomena of anæsthesia in these animals closely resemble those observed in man In order to afford a means of comparison with the results obtained by the French observers on dogs, a few experiments were carried out on these animals

Since it is difficult in any given case to ascertain the exact moment when an animal is actually anæsthetised, the authors have been obliged to take the disappearance of both conjunctival reflexes as a fixed point, and the occurrence of the first asphyxial convulsion of the respiratory muscles as indicative of the lethal stage, and in order to obtain comparable results they have found that the experiments must be made on healthy, well-nourished adults and that the animals must not be in full digestion

From the results of all the experiments it has been found that the amount of chloroform in arterial blood at the moment when the conjunctival reflexes disappear varies between 14 and 27·6 milligrams in 100 grams of blood As others have noticed, the rate of induction of anæsthesia varies slightly in different animals, though the actual body-weight is a negligible factor The curves given in the paper, which have been constructed from the varying chloroform-content of the blood during anæsthesia, show that the rate of induction is a feature peculiar to each *individual animal* The average lethal dose of chloroform in 100 grams of blood is 40 milligrams

After anæsthesia the chloroform is eliminated with extreme rapidity, and though the rate of elimination varies in different animals, the rate of disappearance of chloroform is far more constant than the rate of assumption

A considerable number of experiments devised to ascertain how chloroform when inhaled is distributed in the red corpuscles and plasma show that the drug is primarily associated with the corpuscles, and only gets into the plasma when the anæsthesia is pushed to an extreme point or a high percentage of the vapour is rapidly administered From the results given in Table xvii it appears that no less than 98·5 of the total chloroform in the blood was held by the corpuscles at the moment when the respiration ceased

The view of Desgrez and Nicloux that carbon monoxide is formed in the blood during intense chloroform-narcosis has not been verified by the few observations which were made to determine this particular point

November 8 — "Experimental Investigation as to Dependence of Gravity on Temperature" By L **Southerns**. Communicated by Prof W M Hicks, F R S

The object of this investigation is to determine whether the action of gravity on a given mass varies to any measurable extent when the temperature of the mass is altered Experiments having the same object, but differently carried out, were described by Poynting and Phillips in the Proceedings of the Royal Society, September 1905 about a year after the commencement of the present work These led to a null result, which receives confirmation from the experiments here noticed

The apparatus in its original form was constructed several years ago by Dr Hicks After some modification it was set up in the new university buildings at Sheffield A mass of paraffin oil was used in the experiments This was contained in an air-tight, jacketed calorimeter, and suspended from one end of the beam of a balance, the other end carrying a suitable counterpoise A coil of fine platinum wire was immersed in the oil, and by passing through this an alternating current, the temperature of the oil could be raised to the required degree In order that this might be accomplished while the balance was freely suspended on its knife-edges, the current was conveyed to the coil by means of two wires rigidly fixed to the beam, their ends being pointed and made just to dip into mercury cups which were placed in line with the central knife-edges, and were joined up to the external circuit The connections between the wires and

the coil leads consisted of thin strips of tinfoil The error caused by the expansion of these wires due to the passage of the current was negligibly small The balance was enclosed in a partially exhausted box, the weighings being carried out under a pressure of from 6 cm to 5 cm of mercury.

The experiment consisted in observing (by means of telescope and scale, and a mirror attached to the beam) the equilibrium position of the beam before heating the mass of oil, and noting any deflection of the same which might occur during and after the passage of the heating current. Only very minute, transient deflections were obtained, and as these did not persist it was evident that they could not be due to actual alterations of weight due to rise of temperature The results seem to show that no variation of weight greater than 1 in 10^8 occurs during an increase of temperature of 1° C for the substance used in the experiments

Geological Society, November 7 —Sir Archibald Geikie, Sec R S, president, in the chair —The Upper Carboniferous rocks of west Devon and north Cornwall E A Newell **Arber** After a reference to the previous work in the area the author gives a description of the coast-sections, which display a highly-disturbed sequence of Upper Carboniferous rocks Special attention is paid to two lithological types the Carbonaceous rocks, which contain inconstant and impersistent beds of the impure, smutty coal, known locally as "culm", these beds have yielded plant-remains, and the Calcareous rocks, partly of marine and partly of freshwater origin, consisting of well-marked, impersistent bands of impure limestone, and conglomeratic beds of calcareous nodules embedded in shales One of the limestone-bands, the Mouthmill Limestone, is marine, and contains an abundant fauna, while in others the only fossils are *Calamites suckowi* and *Alethopteris lonchitica* Two distinct and unmingled faunas are present in the rocks one consists of fresh-water lamellibranchs, and the other of marine fishes, cephalopods, and lamellibranchs, and the evidence as to horizon obtained from them agrees with that yielded by the plant-remains —The titaniferous basalts of the western Mediterranean Dr H S **Washington** In 1905 the author visited the volcanic districts of Catalonia Sardinia, Pantelleria, and Linosa He recognises the existence in this region of a hitherto unrecognised petrographic province, in which the basalts contain a remarkably high percentage of titanium The rocks are of Tertiary age Labradorite, augite, and olivine are the essential minerals, with titaniferous magnetite and apatite, and in some cases subordinate nepheline The extent of the region is as yet problematical, and the author points out that along the southern coast of France there are several "basaltic" volcanoes, and it is possible that these may eventually turn out to be connecting links between the rocks of Sardinia and those of Catalonia, or possibly extrusion southward is indicated by the occurrence of phonolite at Maid Gharian, near Tripoli

Royal Astronomical Society, November 9 —Mr W H Maw president, in the chair —Account of recent work at the Royal Observatory, Cape of Good Hope Sir D **Gill** —The systematic motions of the stars A S **Eddington.** The author's conclusions supported Kapteyn's hypothesis that there exist two drifts of stars, one drift moves relatively to the sun with a speed between three and four times that of the other, and the numbers of the stars in each drift are nearly equal —The irregular movement of the earth's axis of rotation a contribution towards the analysis of its causes Prof J **Larmor** and Major F H **Hills.** The movement of the earth's axis of rotation is compounded of a "free precessional" period of 428 days, with irregular disturbances superimposed The authors give a graphical method of setting out the direction and magnitude of the forces giving rise to the irregular disturbance, and hence arriving at its cause The curve representing the movement of the pole about its mean position is first referred to an axis revolving in a period of 428 days The hodograph of the derived curve is constructed, and this is transferred into the corresponding hodograph referred to axes fixed in the earth The last curve then becomes a "torque diagram," showing in direction and relative magnitude the couple or torque acting upon the earth's axis at any date which would account for the observed motion of the pole The forces to which these torques are due may be either internal or external transfer of material on the earth, the latter being in the form of change of ocean level, melting of polar ice, earth quake disturbances, or changes of barometric pressure A numerical estimate of the possible amount of shift due to these various causes was given —The distribution of energy in the continuous spectrum The resolving power of spectroscopes E T **Whittaker**

Physical Society, November 9 —Prof J Perry, F R S, president, in the chair —Exhibition and description of apparatus for students' practical work in physics G F C **Searle.**

THE USE OF PRESERVATIVES

Preservatives in Food and Food Examination By Dr. John C Thresh and Dr A E Porter. Pp xvi+484 (London: J. and A Churchill, 1906) Price 14s net

THERE is much knowledge enshrined in Parliamentary Blue-books, and doubtless some wisdom Very often it remains enshrined in them. A better fate, however, has awaited the report of the Departmental Committee appointed by the President of the Local Government Board in 1899 "to inquire into the use of preservatives and colouring-matters in food-stuffs" Messrs Thresh and Porter have taken this report partly as text, partly as sermon, amplifying it here, compressing it there, and adding, moreover, various allied matters not directly within the purview of the committee, they have produced a volume which will probably be consulted by hygienists when the original Blue-book lies almost forgotten in the archives of the Parliamentary bookseller

The matter is classified into five parts In the first section the authors deal with the various methods adopted for preserving foods and give a general description of preservatives, their pharmacological effects, and the experimental work which has been done upon them For example, Wiley's investigation into the effects of boron compounds upon the human system is summarised, together with Liebreich's criticism of the results, and due note is made of important experiments by many other workers, including Chittenden, Rideal and Foulerton, Annett, and Tunnicliffe and Rosenheim

The second part is devoted to the principal foodstuffs into which preservatives enter, namely, milk, cream, butter, alcoholic and temperance beverages, fruits, vegetables, meat, eggs, and fish Based upon information contained in the Departmental Committee's report, a short account of the substances is given, with figures showing the quantities of preservative used, and notes of the various circumstances affecting its employment

A perusal of these two sections suggests strongly that the present state of affairs is by no means satisfactory as regards the use of chemical preservatives Our policy has been a haphazard one Preservatives of some kind—*e g* salt and vinegar—have been employed as far back as the memory of man carries us The question is asked, Are these long-known substances the best possible for the purpose? Is it not conceivable that modern chemistry might find something better? Quite possibly it may, in fact so far as indicating antiseptics and germicides is concerned, the task is easy But there is the further question how far any substance which is destructive of microbial and parasitical forms of life may also be inimical to the human organism It is a question of quantity On the one hand we have the advocates of various preserving substances—boric acid, formaldehyde, hydrogen peroxide, sodium fluoride, salicylic, benzoic, formic, and sulphurous acids; asaprol, and so on—who argue (1) that by the use of these and other means of preservation food is rendered cheaper, (2) that definite cases of illness or death have rarely or never been conclusively traced to the use of preservatives, and (3) that, on the contrary, during recent years the death-rate has declined, one of the assignable causes of this being the better feeding of the people resulting from cheaper food. On the other hand, it is urged that many cases of illness have, in fact, been indicated as probably due to preservatives At the best these latter have not been proved harmless, and the most we can admit is that we really do not know what are the physiological effects of small amounts of the foregoing substances But they are certainly harmful if taken in quantity, and may be so in any dose which would be effective as a germicide Moreover, even if strong and healthy adults are unharmed by them, there are still children and invalids to consider Again, it has been pointed out that the uncontrolled employment of preservatives is sometimes liable to great abuse without culpable carelessness on the part of any individual user Boric acid, for example, may be added to milk first by the farmer, again by the wholesale distributer, then by one or more retailers, and possibly again by the consumer himself, and each may add the maximum allowable quantity Generally, it may be said that we rarely or never know how much preservative any given food either ought to contain or does actually contain

The policy of our laws has been to allow food-producers a free hand, subject to the restriction that any preservative added shall not render the food injurious to health But has this *laissez faire* attitude been a wise one? True, it leaves the food manufacturer free to experiment—which is so far, good But it gives him the consumer's living body as *corpus vile*—which is not so good

Naturally the consumer has some right of objection, and in any case the question of what is "injurious to health" has always to be fought out in the police court —about the worst place in which to decide such a matter The most diverse decisions have been arrived at, and meanwhile the query whether or not we and our children are being caused unnecessary suffering remains unanswered

What would be the ideal way of treating such a problem if we could start afresh, and impose decrees *modo tyranni?* Surely it would be to say —Let your salt, vinegar, and such like, as having by long usage proved themselves comparatively harmless, remain as they are Let a responsible body be appointed, competent to examine the newer substances, let it hear what is to be said on either side, and let it make whatever experiments may be necessary and practicable to test the evidence And let no preservative or colouring-matter whatever be added to foodstuffs until it has been at least provisionally approved by this responsible authority

If this course is not practicable in its entirety now that a number of more or less dubious substances have gained something of a footing, it is at least possible to a very considerable extent The authors of the volume before us give both sides of the question very fairly—so fairly indeed that we are often reminded of Mr Facing-both-ways But the impression left by a

careful perusal of their statements is that a competent and impartial body is required to, and could, draw up a schedule of substances and quantities which, on a review of all the evidence, might provisionally be considered as reasonably safe to use. The presumption should be that nothing ought to be added to food until it has been proved harmless, not, as at present, that a manufacturer may add anything he likes until it has been shown to be injurious.

Coming now to the remainder of the volume, colouring matters and mineral poisons, which may occur in food and drink, are dealt with in the third part, and the following section—a long and important one—is devoted to the study of unsound food. Notes on the principal diseases of animals and upon *post-mortem* appearances are appended, and directions are given for the bacteriological examination of shell-fish and of milk and other dairy produce, as also for the detection of toxins and ptomaines in foodstuffs.

The concluding section is devoted to the chemical examination of foods for preservatives and colouring matters, with a chapter on legal points. For the most part the analytical processes described are well-known methods, conveniently collected here, but otherwise calling for no special comment. In passing, however, it may be remarked that mannitol is easier and cleaner to use than glycerol in the volumetric determination of boric acid.

On the whole the volume is a trustworthy production, and may be accepted as the most useful compendium of the subject yet published. C. Simmonds.

MATHEMATICS OF BODILY MOVEMENTS.

Theoretische Grundlagen für eine Mechanik der lebender Körper. By Otto Fischer. Pp. x+372. (Leipzig: B. G. Teubner, 1906.) Price 14 marks.

A FAMILIARITY with the structure of the human body is but rarely combined with a competent knowledge of mathematics. So far as one may judge from published works, Prof. Otto Fischer is the sole representative of this combination of talents in Europe. But his attainments, from their very singularity, carry with them certain disadvantages; although he has diligently applied the methods of the mathematician to the elucidation of the movements of the human body for the last twenty years, he has raised neither rival, disciple, nor critic, his many publications have failed, apparently, to attract the attention of writers of text-books on anatomy and physiology. Prof. Fischer expresses the hope that his book will appeal to mathematicians and physicists on the one hand, and to anatomists and physiologists on the other, he has employed the most intelligible anatomical terms and descriptions for the benefit of the first, and reduced the necessary mathematical formulæ to their simplest expression for the second. Notwithstanding these attempts to form a common ground where mathematicians and anatomists may meet on equal terms, the writer of this notice finds the mathematics of this work difficult and wholly to be taken on trust, and he believes the vast majority of anatomists will experience a similar difficulty. Nor does he believe that the pure mathematician will easily understand the action of such muscles as the "abacus," "short head of the biceps," or "semi-membranosus," nor have a definite conception when he is told that the centre of gravity for the head lies between the "dorsum sellæ" and "posterior perforated lamina."

The initial difficulties which the mathematician and anatomist will experience in studying this book may lead to its great merit being overlooked. In medical text-books the actions of muscles and of joints are described in crude snatches; when the student has finished his study he has no knowledge of the mechanism of the body as a whole. Prof. Fischer's aim is to give a picture of the living, moving body as a complete machine, to estimate the manner in which the muscles work in producing definite movements of the body, and the amount of force expended in the production of these movements. For the purpose of his investigation he has divided the body into fourteen segments or masses, viz. the head, trunk, upper arm, fore arm, hand, thigh, leg, and foot, each of these he treats as a rigid mass; he estimates the centre of gravity for each. The centre of gravity for the trunk he found to be situated near the front of the upper border of the first lumbar vertebra. The mass or weight of each of these parts is estimated, the trunk forming, in the average body, rather more than two-fifths of the whole. The methods applied to the study of machines cannot be used for the human body, where the joints have no fixed axes or fixed points. These difficulties Prof. Fischer seeks to overcome by establishing theoretical fixed axes and fixed points for the various joints, he simplifies his problems, too, by the use of what he terms "mass systems." Although Prof. Fischer has not been altogether successful in reaching the non-mathematical mind, we are certain he has given us in this unique book matter which both physicist and biologist may study with advantage.

GOETHE AS MINERALOGIST AND GEOLOGIST.

Goethes Verhältnis zur Mineralogie und Geognosie. Rede gehalten zur Feier der akademischen Preisverteilung am 16 Juni, 1906. By Dr. G. Linck. Pp. 48. (Jena: G. Fischer, 1906.) Price 2 marks.

THE poetic genius and fascinating personality of Goethe have so dazzled the world that the ordinary reader of "Faust" has never so much as suspected that its author could claim to be a distinguished man of science. Some, perhaps, who have studied the life of the poet may be aware of his discoveries in biology and his speculations in botany, others, again, may have heard of his excursion into the field of optics, and may have marvelled at the amazing aberration of his genius which led him to regard his unhappy attack on the Newtonian theory of colour as the proudest and most valuable achievement of his life; but that he accomplished anything of worth in mineralogy and geology is known to very few.

It is, therefore, well that the professor of mineralogy

and geology at Jena has attempted to do justice to this side of Goethe's activity. Realising the danger of anachronously misrepresenting Goethe's position by attempting to interpret his work in the light of our present knowledge, Prof. Linck has wisely allowed Goethe to explain himself in extracts from his published writings and correspondence. Goethe appears to have been attracted to the study of mineralogy partly by the reopening of the Ilmenau mines and partly through the influence of the Freiberg school. Further, his official position brought him into contact with mining and geological problems, and his business instincts led him to take an interest in any discovery likely to be of practical use.

Goethe, in fact, was by nature a realist, and even his muse was happiest when inspired by a striking event or by a beautiful scene. His realistic tendencies led him to become an ardent collector of minerals, rocks, and fossils, which he regarded from a natural history point of view. But he lived in a time when the classification of minerals by their more obvious external characters and by their mode of occurrence was passing away. On the one hand, analytical chemistry was revealing their composition; on the other, crystallography was reducing to order the apparent complexity of the crystal forms. Goethe, however, held by the old system. He realised, it is true, the importance of chemistry—"I cannot get a step further in mineralogy without chemistry"—but it was a study for which he appears to have had but little aptitude. His appreciation of crystallography was smaller still, witness his statement, "Crystallography is not productive—and leads to no results, especially now that so many isomorphous bodies have been discovered of different compositions." Goethe appears, indeed, to have regarded the progress of these sciences with some misgiving, for he says:—"Mineralogy is in danger of being devoured by crystallography, where form is all important. It is in danger of being devoured by chemistry, which looks only for general laws and is indifferent to form. It may also be in danger of being devoured by geology, for the latter is only concerned with modes of occurrence." As an adherent, then, of a system which had attained practically the fullest development of which it was capable, the field open to him was not extensive, but within its limits he did good work. His description of the Carlsbad felspar twins, for example, was excellent, and we owe many interesting observations to his studies on crystal genesis and on the occurrence and associations of minerals. Among his collections, those from the neighbourhood of Carlsbad were the most important, but Thuringia, the Harz, and Italy were laid under contribution as well, for the mineralogist must be like a stag and browse irrespective of frontiers.

Early in his studies Goethe felt his weakness on the scientific side, and to remedy it caused W. Voigt to be sent to Freiberg. Voigt on his return instructed him in nomenclature, and he began to arrange and label his collections, for "every properly recorded observation is invaluable to posterity." His activity as a collector soon impressed on him the importance of good maps, and the interest thus stimulated led to the preparation of a mineralogical map of the Ilmenau district, subsequently extended to neighbouring regions. It bore further fruit in several practical suggestions as to the best method of printing and colouring such maps. The colour scheme employed to-day is in essentials that proposed by him.

Perhaps Goethe makes his greatest claim to be considered a geologist by his attitude towards the problem of the history of the earth. Living at a time of conflict between Neptunists and Vulcanists, his mind was too well balanced to allow him to become a bigoted partisan or the slave of a hypothesis. The uniformity of nature was his watchword, and he never lost sight of this principle, whether discussing the erratic blocks of Northern Germany or the basalts of Bohemia.

At the conclusion of his review of Goethe's essays in mineralogy and geology, Prof. Linck asks the pertinent question, Are such studies to be put aside with a smile and a shrug of the shoulders as the well meant efforts of an amateur and nothing more? Prof. Linck thinks not. He points out that many contemporaries well qualified to judge thought highly of the work, and he holds that Goethe is justly entitled to an honourable place among the pioneers in mineralogy and geology. We venture to think that anyone who follows the case presented in his pages will endorse his verdict.

THE CHEMICAL STRUCTURE OF CELLULOSE.

Researches on Cellulose. II. (1900–1905.) By C. F. Cross and E. J. Bevan. Pp. xi+184. (London: Longmans, Green and Co.) Price 7s. 6d. net.

IN the course of their extended researches on the chemistry of cellulose the authors of this work have gradually become dissatisfied with all the numerous attempts which have from time to time been made to represent the chemical structure of this substance by means of ordinary constitutional formulæ. The fundamental basis for such a representation, the knowledge of the molecular weight—has always been and is still lacking, and in its absence the chemist has perforce limited himself to endeavouring to assign a chemical constitution to some comparatively small unit containing six or some multiple of six carbon atoms, and has usually regarded the complete unknown molecule of cellulose as a polymeride of this. A certain measure of success has attended these efforts, particularly as regards the relation of the final products of such processes as nitration or hydrolysis to the original unit.

The authors, however, consider all such formulæ to be totally inadequate to express the greater number of the chemical changes which cellulose is capable of undergoing. In place of the purely chemical idea of cellulose as a complex polymeride of preformed groups of rigid configuration, they propose to substitute the conception of cellulose as a colloidal aggregate which may be considered to react "as a labile complex of groups of varying dimensions representing a state of matter somewhat analogous

to that of a saline electrolyte—that is, it reacts rather as a solution-aggregate than by a succession of molecular combinations, the masses actually reacting following the stoichiometrical ratios proper to the dimensions of these ultimate groups, and retaining their relationship in the aggregate, which is thus progressively modified by the entrance of the new groups" (p 7)

Owing to the prevailing ignorance as to the nature of colloids and the relation of this condition of a substance to its chemical character, both the language and the ideas employed by the authors in the development of their thesis are, as they themselves admit, somewhat vague, and it is difficult to realise exactly wherein lies the advantage of the new standpoint over the old view of cellulose as a highly complex molecule, coupled with the recognition of the fact that both the parent substance and many of its derivatives are only known as colloids There can, however, be no doubt that sufficient attention has not hitherto been paid to this cardinal fact of the colloidal character of cellulose, and the authors do good service by insisting upon it and showing very clearly how this conception may serve to suggest many hopeful lines of investigation on questions of scientific and technical importance

The first section of the book contains the development of these ideas, together with a general account of the chemistry of cellulose In the second section are brought together the more important researches on the subject of cellulose which have appeared during the period 1900–5 An impartial abstract of each investigation is given, followed by critical notes on the bearing of the results on the great question of the chemical structure of cellulose The third and concluding section deals with the progress made on the technical side of the subject during the same period This book therefore forms a supplement to the two volumes which have preceded it, but it is valuable, not merely as a compendium of the latest researches on cellulose, but much more as a thoughtful and suggestive contribution to our knowledge of the chemical and physical structure of this important natural product ARTHUR HARDEN

OUR BOOK SHELF

Cours d'Astronomie Première partie Astronomie Théorique By H. Andoyer Pp 221 (Paris A Hermann, 1906) Price 9 francs

THERE is no preface to explain the scope of Prof Andoyer's book, but it appears to consist of the notes of a course of lectures on spherical astronomy Now, it is characteristic of lecture-notes to offer definitions in place of explanations, also, they have a tendency to disintegrate into a bewildering array of unconnected problems The book has these defects But as an exposition of the art of manipulating the very cumbersome formulæ of spherical trigonometry which pervade astronomy, it will fulfil a useful purpose The mathematical treatment is good and concise, moreover, the problems treated are mostly of a severely practical character The author has wisely taken as his guide the Connaissance des Temps, he refers to it continually, and there is very little in the book which has not some direct bearing on the use or construction of its tables

The usual subjects are fully treated, refraction, parallax, aberration, precession, and nutation, there is a brief account of motion in an ellipse. The chapter on the geocentric motions of the planets is not very satisfactory, the student who has followed the lengthy investigations of the preceding chapters might safely have been offered something more advanced and more approximate to the practical problem than the very rudimentary theory here given The apparent motion of satellites is in like manner inadequately treated The last chapter, which deals with eclipses, is, perhaps, the best feature of the book, solar eclipses are treated in a very thorough and interesting way The general accuracy and precision of the book are admirable, the approximations and assumptions made are always clearly stated Occasionally, however, precision is carried to excess, as for instance, when the proper motion of Arcturus is given in seconds per *tropical* year (p. 141)

It is a pity that the book is not *printed* in the usual way It appears to have been reproduced in facsimile from the written manuscript This is a needless sacrifice of clearness, and must to some extent diminish its value as a book for reference A S E

Les Révélations de l'Écriture d'après un Contrôle scientifique By Alfred Binet Pp viii+260 (Paris Félix Alcan, 1906) Price 5 francs

IN this book M Binet, the well-known experimental psychologist of the Sorbonne, describes an investigation of the art of telling intelligence and character from handwriting After some preliminary inquiries to ascertain how far "graphologists" are able to recognise sex and age by means of writing, M Binet submitted to several experts specimens of the handwriting of people of great intellectual eminence, such as Renan, Dumas *fils* and Claude Bernard, together with others obtained from persons known to be of ordinary intelligence The general result was to show that, though the experts were more often right than wrong, they were liable to the grossest errors, as in one case in which Renan was judged to be of mediocre and uncultivated intelligence, an opinion into which the expert appears to have been led by the repetition of a word in the sample

In the estimation of character a similar result was obtained This was tested by submitting to the graphologists specimens of the handwriting of notorious criminals to be distinguished from the writing of people of good moral reputation Here again the experts were usually more or less right, but bad mistakes were made, as when a man who had murdered his mother with every circumstance of brutality was judged to be a young girl, "*douce, modeste, et peu coquette*" In the simple distinction of the two classes of people concerned in the tests, the number of correct answers was distinctly greater than should have been expected from chance, and this preponderance of correct judgments was greater in the estimation of intelligence than in that of character, but it is not clear that clues derived from the subject-matter of the samples of writing were altogether excluded in the former case

In M Binet's hands the graphologists themselves became the subjects of investigation, and it may perhaps be regarded as evidence that their art has a scientific basis that some of the experts showed themselves greatly superior to others, under an experimental procedure which deprived them of many of those adventitious aids on which it is probable they usually rely

The Cyanide Process By Alfred S Miller Second edition, revised and enlarged Pp viii+95, with 29 illustrations (New York John Wiley and Sons; London Chapman and Hall, Ltd, 1906)

THIS little book may be of value in giving general ideas on the cyanide process to those who know nothing about the subject The possessor of the book may be put in a position to understand what is meant by the various phrases with regard to cyaniding that appear in the technical Press It is, however, the least practical of manuals, and its statements, sometimes self-contradictory and sometimes mistaken, must be accepted loosely and generally without too close examination This is the worst that can be said of it, and if it is read cursorily there is no reason for the reader to be misled On the contrary, he may be enabled to converse intelligently on the subject

Highways and Byways in Berkshire By James Edmund Vincent With illustrations by Frederick L Griggs Pp xiii+430 (London Macmillan and Co, Ltd, 1906) Price 6*s*

ALL readers who are familiar with this attractive series will welcome the most recent addition to it The style of production, the illustrations and the spirit of the author will together ensure the volume a wide popularity Mr Vincent is never dull and every aspect of the country side with which he is dealing—be it historical, geological, or sociological—is made to contribute something of interest The book will certainly serve as an invaluable companion to the reader who decides to explore Berkshire for himself, telling him what spots to seek diligently and indicating the districts that may be treated lightly The indolent man, who eschews travel as troublesome, will be able without leaving his armchair by the fire, now that he can have the assistance of Messrs Vincent and Griggs thoroughly to enjoy Berkshire scenes, make the acquaintance of Berkshire men and women and learn the importance of the county in English history

LETTER TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Geological Survey of Canada

AS one deeply interested in the success of the Geological Survey of Canada, I cannot but regret the letters which have appeared in NATURE concerning the appointment of Mr Low to the directorship of the survey As a result of these letters misapprehensions will certainly remain in the minds of the readers of NATURE concerning this appointment, which it would be impossible to dispel without a detailed statement of the full facts of the case There are however, two statements contained in the letter which appeared in the number of NATURE dated July 12 (vol lxxiv, p 245) which reflect directly on Mr Low's character and standing, and which, in common justice to that gentleman, should not be allowed to pass unchallenged

The first of these statements is that "party politics and not geology have been in question in regard to Mr Low's appointment," and the second is that "Mr Low is quite unknown in the geological world"

With regard to the first of these statements, I may say that when the Canadian Government—for reasons which it is not my purpose here to discuss—decided that they would not appoint Dr Bell director of the Geological Survey of Canada, they proceeded to select, quite irrespective of all considerations of party politics, the best man who was available in Canada to fill that position They accordingly offered the position in question in succession to two geologists holding chairs in leading Canadian universities Both these gentlemen, however preferred to retain their university connection, and declined the position The Government then decided to promote Mr Low, who was one of the senior field geologists on the Canadian Survey, to the position of director

Mr Low received his geological training at McGill University, taking at the time of his graduation honours in geology He received his geological instruction from Sir William Dawson After graduation he was at once appointed to a position on the Geological Survey of Canada, and was assigned the task of mapping various areas of the pre-Cambrian rocks of the northern portion of the Dominion of Canada The work which he carried out in the region of the great lake Mistassini is well known and he was subsequently sent by Dr G M Dawson to undertake the exploration of that great tract of north-eastern Canada which comprises the Labrador peninsula While others lost their lives in endeavouring to penetrate into the interior of this great unknown land Mr Low traversed it repeatedly from north to south and from east to west, and embodied the results of his work in a series of valuable reports on the geography, geology and mineral resources of this great region, the final report being accompanied by a large four-sheet map of the whole region showing its geological structure along the various lines of traverse We owe to Mr Low practically everything that we know with regard to this great tract of country His observations on the surface features of this region which was one of the chief centres of ice dispersion in the Glacial period, are of great importance in connection with our studies of glacial geology

On the completion of this work in the Labrador peninsula Mr Low spent a year and a half in the investigation of the iron-ore resources of the region about the southern portion of Hudson's Bay and more especially on the islands in the Bay, where great bodies of low-grade iron ore occur

Still later, when the Dominion Government decided to take formal possession of the Hudson Bay region and the islands of the Arctic archipelago they selected Mr Low to take charge of the expedition which they sent to the north for that purpose Mr Low accordingly, in charge of the ship *Neptune*, pushed his way far north through the Arctic archipelago to the Arctic Sea taking formal possession of the various Arctic islands in a cruise which lasted for sixteen months and was accomplished to the satisfaction of the Government in every respect

For these various northern explorations Mr Low received the Gill award from the Royal Geographical Society

The reason that Mr Low's name is not more widely known in Europe is due chiefly to the fact that his contributions to the various geological magazines and transactions have been comparatively few in number the results of his work being published chiefly in reports both voluminous and valuable which were made to the Geological Survey of Canada, and which are to be found in their annual volumes These naturally are read chiefly by those particularly interested in the geology of Canada and consequently do not reach a wide circle of readers

Mr Low also, it may be mentioned is a Fellow of the Geological Society of America, a body composed solely of professional geologists, and one basing its election to fellowship solely on valuable contributions to geological science

The above facts I think, afford an adequate answer to the statement that Mr Low is "quite unknown in the geological world"

In conclusion, it may be safely stated that in appointing Mr Low to the directorship of the Geological Survey of Canada the Dominion Government has secured the services of a gentleman who has not only a sound geological training and an extensive experience in field geology but also a gentleman of initiative and administrative ability in the prime of life and one whose appointment has been well received both by the geologists of the Dominion and by the representatives of the mining interests with which our Geological Survey is so closely identified

FRANK D ADAMS

McGill University, Montreal October 31

NOTES ON ANCIENT BRITISH MONUMENTS

I

The Aberdeen Circles A Letter to Dr Angus Fraser

DEAR DR FRASER,

I told you when leaving Aberdeen that so soon as I had discussed the observations of the stone circles I was enabled to make, thanks to your kindness in placing your motor-car at our disposal, you should be the first to know of the results

Here is my report Before I refer to the observations themselves I will just say why I was so anxious to have a look at your circles During the last year my wife and I had photographed and measured several circles in Cornwall and Devonshire We found outstanding stones, apparently to indicate certain directions in which observations should be made from the centre of each circle I studied the chief directions astronomically, and found that they might have been used to observe the rising places of stars and of the sun at different times of the year in each circle, and that practically the same places of star and sun rising were observed in all the circles This indicated a general use we were dealing with a system, and not with a chapter of accidents Each circle might have been a town clock and farmer's almanac combined, whatever other purpose of utility it may have served

I gave an account of this work in my book "Stonehenge," and very briefly in a letter to *The Times* (July 30, 1906)

Now before I went to Aberdeen Mr A L Lewis, a great authority on these ancient monuments, had told me that your circles were different from those in south England In each of your most perfect circles there is, instead of a *standing* stone outside the circle a *recumbent* stone inserted between two of the stones of which the circle itself is composed Not only had I got this information from Mr Lewis, but I had had the advantage of seeing the many plans prepared for the Gunning fellowship reports by Mr Coles, the assistant keeper of the Museum of Antiquities at Edinburgh

The question, then, was, might the *recumbent* stones in the Aberdeen circles play the same part as the *outstanding* stones in Cornwall and Devonshire? If so, of course they could have been used with the same object, that, namely, of indicating a direction, they would only represent a difference of design, not of purpose

An inspection of some of the available plans suggested that in the recumbent stone and its supporters we had a special form of "cove," the direction required being indicated by a line *across the circle* perpendicular to the length of the recumbent stone

If this were so, we should find the Aberdeen *recumbent* stones placed *at right angles* to the chief direction lines to the *outstanding* stones found in S England, lines used for the star- and sun places I have detailed in my book "Stonehenge," and therefore dealing with practically the same declinations, latitude and heights of hills being taken into account

Now to settle this point it was necessary to obtain trustworthy azimuths of these directions, and of the angular height of the horizon in each direction, and it is here that I owe so much to the kindness of friends in Aberdeen which I am most anxious to acknowledge The University authorities, represented by Prof Macdonald, lent me a theodolite, you placed your motor-car at our disposal, and Dr Milne was good enough to suggest circles to examine, and accompanied us to the sites

The circles examined were Sunhoney, Midmar, Auchquhorties (Fetternear), Raes of Clune, and Old Bourtree Bush

Friday, September 28 —Sunhoney, lat. N 57° 8′, az N 46° E, horizon 4° high These numbers are only approximations, for the recumbent stone is curved, and the horizon is covered by trees Midmar, lat 57° 8′, az N 42° E, horizon 1° 30′ high The alignment was taken on the stone across the circle, its line of direction being, apparently at right angles to the front surface of the recumbent stone The height of horizon is doubtful, in consequence of trees

Saturday September 29 —Auchquhorties (Fetternear), lat N 57° 16′, az N 19° E, horizon 2° 30′ high (assumed half-way up the trees)

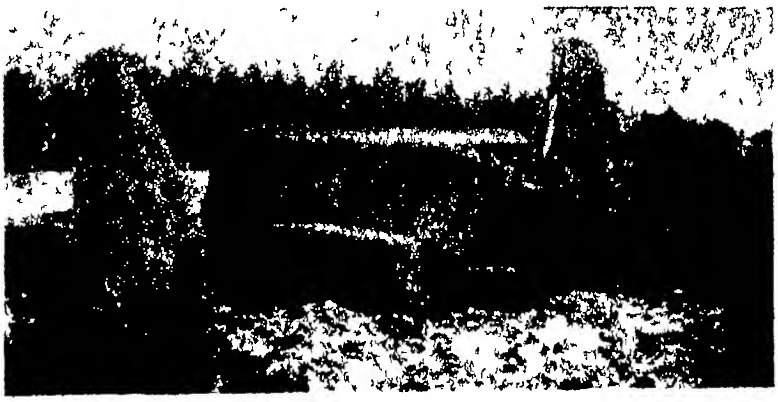

Photo by Mr Ritchie

FIG 1 —The recumbent stone at Auchquhorties showing supporters and other stones directed to the centre of the circle

Monday, October 1 Raes of Clune, lat N 57° 5′ No measures were made, as the ground near the recumbent stone had been excavated, and the stone disturbed Mr Braid, who had taken much trouble to enable us to find the site, and whom we met near it, promised to make a new survey of this and the other adjoining circles for examination at some future time Old Bourtree Bush, lat N 57° 3′, az N 270° W, horizon not measured

Before I discuss these measurements in detail, let me say that the first result which stares one in the face is very remarkable

The measurements of the first five circles, which were selected at random, show that two, like the restored Stonehenge, could watch the sunrise at the summer solstice The direction line of another resembles those of a dozen circles in England, built, as I hold, to watch the rise of the clock-star, and the only other one measured is directed to the sunset at the equinoxes

To enter into details I take the magnetic variation for 1906 at 18° 30′ W; this then has to be applied to the compass bearing to get the *true* azimuth I also give a table of the solstitial azimuths, taking heights of hills into account, for lat 57° —

	True Azimuths Summer	Winter
With sea horizon	N 41 0 E	S 44 46 E
" 1° elevation	43 40	42 10
" 2° "	46 16	39 30
" 3° "	48 20	36 46
" 4° "	50 24	33 56

These values apply in a general way to both Sunhoney and Midmar. The difference of azimuth observed arises from the fact that there is, roughly, a difference of 2° in the angular height of the horizon at the two places. I attach greater weight to the measures at Midmar, as the direction was taken to a stone on the other side of the circle. It may be that this way of making the direction line "siccer" was generally taken; the plans suggest but do not prove it.

Let us, then, look at the Midmar result a little more closely. My rough measures gave an azimuth of N. 42° E. According to the above table the azimuth of the solstitial sunrise to-day, with hills 1° 30′ high, is practically N. 45° E. There is a difference of 3°.

Now in your latitude at the solstice, the sun when it rises or sets grazes the horizon for a long time, the direction of its apparent motion is only slightly inclined to the horizon. To-day it is about 27°. A change in the sun's declination due to the change in the obliquity of the ecliptic, which was greater in past times, will therefore produce a great change in the azimuth of sunrise. Thus to give figures ready to my hand, if instead of the present declination of 23° 27′ we take 23° 50′, the declination at B.C. 1000, according to Stockwell's calculations, the present azimuth of N. 44° 58′ E. (with hills 1° 30′ high) becomes N. 43° 57′ E.

Now this is a degree nearer my value of the azimuth, and if that value is not very much out, and if the recumbent stone was arranged in relation to the solstice, it is clear that the Midmar stones were set up more than 3000 years ago.

To carry this inquiry further, observations much more complete than mine, including observations of the sun with accurate time to get the astronomical bearing directly, are required. We want, too, observations in winter when the leaves are off the trees, so that the height of the horizon can be accurately measured.

To such observations *in your high latitude* I attach very great importance, since changes in direction due to the change of obliquity of the ecliptic can be considered under much more favourable conditions than in S. England in the case of circles connected with the sun at a solstice.

I pass to the azimuth N. 19° E. at Auchquhorties. In S. England, as stated in "Stonehenge," the available clock-stars were Arcturus and Capella. But this was for lat. N. 50°. How about lat. N. 57°? I find that for this latitude these two stars were the only ones available for part of the time, and, further, that Castor might have been used at another time.

In the district round Aberdeen, and especially to the westward, the height of the horizon varies greatly. How this affects the star question, and how it is needful for archæologists to take account of it, will be gathered from the accompanying diagram, which Mr. Rolston has been good enough to prepare.

To show the use to be made of it, let us take the observed azimuth at Auchquhorties, N. 19° E. With hills 2° 30′ high, we find that if a star were really in question, it must at the time of circle-building have had a north declination of 33°. This was Capella's declination about B.C. 1640, and Arcturus's about B.C. 600.

There is a difference of a thousand years, and if further inquiries show that either or both of these stars may have been used in connection with these circles, some progress will surely have been made which it seems cannot be made without it.

It will be clear that when *final* observations have been made at Midmar and other circles which may be connected with a solstice, the sun and star dates may be compared, and each may throw light on the other. For instance, if the final values for Midmar come anywhere near my provisional ones, we shall have an argument in favour of Capella as against Arcturus at Auchquhorties, for it is fair to assume that the circles in any one region, whether solar or stellar, were started at *about* the same time, at least, the evidence furnished by the Cornish monuments is in this direction.

Photo by Lady Lockyer.

FIG. 2.—The recumbent stone and its supporters at Auchquhorties. View from the back looking across the circle.

The result of such detailed inquiries as these will do much to enable us to form an opinion touching the possibility of astronomical considerations having been taken into account by the builders of the monuments.

I wish to plead for the examination of these circles in the widest possible sense. As I have said, they may have served several purposes, some of them at present undreamt of, and in this connection I protest against the logic of those who hold that because graves have been found in them they were constructed wholly for purposes of burial, and that no other considerations were in the minds of those who set up the stones. It is the same thing as to say that because graves are found in our churches the churches themselves were not built for the worship of God.

While I am writing to you I see in the *Scotsman* (November 8) that recent explorations at Fernworthy Circle, on Dartmoor, have shown that every inch of its area is covered with wood charcoal "In fact, fires seem to have been kindled all over the circle, for every scoop of the pick and shovel which was removed from the floor displayed charcoal." Now this looks much more like the result of a succession of Beltaine, or other fires, year after year than of burials, and there would be the closest connection between the orientation of the circle which showed when the time of festival had arrived and the fire which proclaimed its advent

But any way, the more uses were made of the circles the better they are worth investigating

I have no doubt that connected with your magnificent University (and I do not forget that I am now one of you) there is, or soon will be, a strong School of Archæology, happier than most such schools in that you have a fine field of exploration at your doors, for there are 175 stone circles in your shire alone, shown in the Ordnance maps

Now let me keep to my own parish and try to point out that a research touching the application of the orientation theory to these circles would certainly be a source of the greatest interest to the researcher.

First he would have to arrange his observations so that he could discuss the value or the futility of the theory taken as a whole, and then if the theory proved valid he would have to hunt down the use of the May, solstitial or equinoctial year and the stars used as clock-stars The thing bristles with plots for detective stories

What a time the alumnus of this School who has best studied the methods of Sherlock Holmes will have!

First of all, of course, he must visit the ground, that is, the circles, and among the large number he need consider, in the first instance, only those that have well-marked recumbent stones On this point he should consult Mr Ritchie, of Port Elphinstone who has, I believe, photographed them all (and let me say here how grateful I am to him for the gift of several mounted prints one of which, with his permission, I have copied above) Next, let him neglect the names, weights, and colours of the riders—I mean the stones—and simply determine the azimuth of the line at right angles to the recumbent stone taken across the circle, and the height of the horizon in that direction Even the university theodolite is not absolutely necessary, an azimuth compass, and a "clinometer" which can go in the waistcoat pocket, will suffice for a reconnaissance

Now for "clues"

Are the azimuths all helter-skelter, that is, distributed anyhow, among the four quarters of the circle from 0° to 359°? (If so, the culprits need not be sought among astronomers, and the orientation theory is all moonshine)

Is an azimuth, say between N 10° and 25° E, pretty common or quite exceptional? (If pretty common, this will strengthen the view that we are dealing with observations of a clock-star and that blind chance has nothing to do with the inquiry)

Is there any relation between the azimuths and the amount of squaring of the stones? (If so, as the non-squared stones are most probably the oldest, if the azimuths decrease as the squaring gets more pronounced we are dealing with Capella; see diagram)

Is there another group of azimuths between N 40° and 48° E? (If so, as this is the solstitial alignment, it will strengthen the astronomical view.)

Are there any azimuths about N 58° E.? The rising place of the sun at the beginning of May at the Beltaine feast? (If not, we have an argument against great age, as the oldest sun alignments in

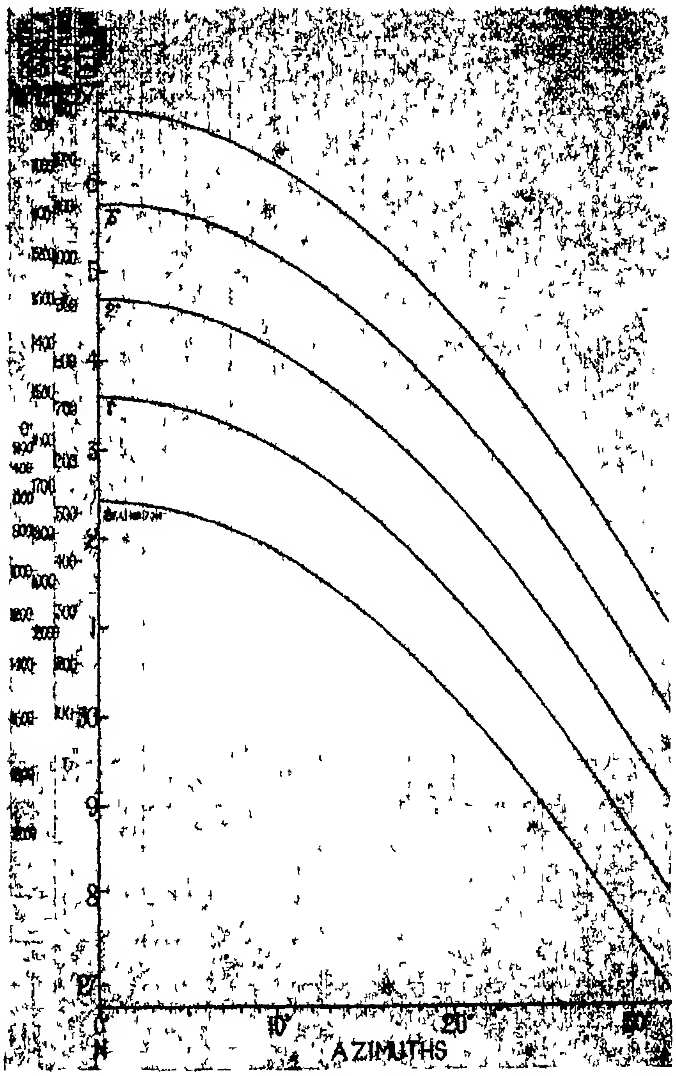

FIG 3—Showing the dates at which the stars Arcturus, Capella and Castor rose at the azimuths indicated, the heights of the horizon being taken into account

Cornwall and along the west coast deal with the May-year)

Is the Aberdeen form found anywhere else? (If so, the other regions in Europe or elsewhere to which it is common may be regarded as in some way connected with the form)

Is it a general rule that the heights of the stones decrease from the recumbent stone to the opposite side of the circle? (If so, the relation of this to the naos at Stonehenge must be considered)

I hope I have succeeded in showing you that there are many points of great interest connected with

your Aberdeen stone monuments which are well worth investigation.

I hope, also, that Aberdonians will see that the necessary work is done. How I wish I could be with you to help in it, and renew the pleasures you allowed my wife and myself to feel, going about among the relics of a long bygone past in your most modern motor car.

Always sincerely yours,
NORMAN LOCKYER

APPLICATIONS OF THE MICROPHONE PRINCIPLE

AN interesting booklet upon applications of the microphone principle has been written by Messrs. Jensen and Sieveking, of the physical laboratories in Hamburg and Karlsruhe.[1] By the term "microphone principle" the authors mean all those phenomena which are due to the change of ohmic resistance between loose contacts. The memoir contains a very exhaustive collection of what is to be found scattered in scientific literature from the time of Munck of Rosenschoeld, to the present day. The explanation that in loose contacts the nearer approach of the particles resulting from the application of pressure is the cause of the diminished resistance observed, is ascribed to du Moncel and Beetz, who gave it almost simultaneously, though independently. Among the early practical applications of this property of loose contacts was Hughes's induction balance, which is so well known that no lengthy reference need be given here. A less known though also interesting application may, however, be mentioned, namely, the demonstration of nodes and antinodes in acoustic waves in cylindrical vessels. By lowering a small microphone into the cylinder, Fossati succeeded in locating the position of the nodes and antinodes by means of a telephone receiver connected with the microphone. The sound waves impinging against the loose contacts produce a rasping sound in the telephone, which vanishes when the microphone reaches the position of a node. In a darkened room minute sparks may be seen between the microphone plates when the microphone is in the position of an antinode.

Another acoustic application of the microphone made quite recently by Hebb is the determination of the velocity of sound. He uses two parabolic mirrors facing each other, and placed on the same axis. The one is fixed, and the other can be moved to a greater or lesser distance. In the focus of the first or fixed mirror is placed a tuning fork and a microphone, in the focus of the movable mirror a second microphone. The secondary of an induction coil having two primary windings is connected to a telephone. The primary windings are connected each with a battery and one of the microphones. The sound waves of the tuning fork act directly on the microphone next to it, and the reflected sound waves on the microphone in the movable mirror. It is easy to see that the loudness of the tone given out by the telephone depends on the frequency of the tuning fork, the distance between the two mirrors, and the velocity of sound. If both microphones receive antinodes at the same time, the tone is loudest, and if there is a phase difference of half a period between them the tone is weakest. Now the phase difference depends on the distance between the mirrors, the length of the acoustic wave, and the frequency. By first carefully determining the latter, and then finding the position of strongest and weakest sound, Hebb was able to determine with great accuracy the velocity of sound. He found it to be 331.29 metres, the probable mean error being only 0.04 m.

The attempts to use the microphone in seismography do not seem to have led to any practical or trustworthy result. Rossi, in 1887, used a microphone consisting of a silver plate and pointed lever in his underground observatory near Rome, and noticed that the telephone gave out sounds which were unmistakably the effect of seismic movements, and when afterwards the apparatus was tranferred to Vesuvius and came under Palmieri's observation, a general agreement between the sounds in the telephone and the records of the seismograph was observed, but the difficulty of separating sounds due to other causes seems to have stood in the way of further developments. Nevertheless, the authors think that the microphone may be made a seismographic instrument of great sensitiveness.

An ingenious application of the microphone for the detection of fire-damp has been made in France by Hardy. If the sound waves of two pipes of equal pitch impinge on microphones connected in series with a telephone a clear note is heard, but if one of the pipes emits a but slightly different note there will be beats heard in the telephone. Now if one pipe is on the bank and the other underground, the latter, if there be fire-damp, will be blown with air of a different density and emit a different note. The telephone, by sounding beats, will then give warning of the presence of fire-damp. The apparatus when tested with coal gas showed great sensitiveness. An admixture of but 0.1 per cent. gave three beats in twenty seconds, and an admixture of 1 per cent. gave thirty beats in twenty seconds.

The memoir deals very fully with the use of the microphone in telephony, including the production of graphic records such as are given by the instruments of Nernst, Lieben, Poulsen, and others. Also the use of the microphone in wireless telephony is touched upon. The most directly useful part of the memoir is, however, a very full account of the work done by a large number of experimenters in order to ascertain the best composition of the material forming the loose contact of the microphone, its mass, area of contact, specific pressure and other determining factors as regards strength and clearness of sound.

The connection between the microphone and wireless telegraphy is not obvious, and the authors deal with this part of their subject very briefly. One sentence is, however, so interesting that it may, in conclusion of this short review be quoted verbatim. The authors say:—"Already in 1879 Hughes has used the influence of spark discharges on microphonic resistances for wireless telegraphy over a distance of 400 meters."

GISBERT KAPP.

[1] Anwendungen des Mikrophonprinzips. By Chr. Jensen and H. Sieveking. (Hamburg: Graefe and Sille.)

SIR EDWARD J. REED, K.C.B., F.R.S.

THE death of Sir Edward James Reed on November 30 brought a long, useful, and highly distinguished career to a close. He was in his seventy-seventh year—full of activity, with mind as vigorous and interests in life and work as keen, as ever. He was an active worker to the end. For the greater part of the last half-century he was the most prominent naval architect of his time. His influence during that long and important period in the progress of naval construction was one of the most potent forces that shaped its development and improvement. That influence was exerted not only by his work and teaching but also by constant and earnest efforts from his earliest days to promote the scientific education and training of young men

for the pursuits of naval architecture and marine engineering, and to raise the scientific standard and professional status of those important branches of engineering

Edward James Reed was born at Sheerness in September, 1830 He received a thorough practical training in the Royal Dockyard there, and was afterwards a student of the School of Mathematics and Naval Construction in Portsmouth Dockyard, where he received the highest education in the science of naval architecture that was obtainable in this country On passing out of the Portsmouth school he was given a subordinate appointment in Sheerness Dockyard, but he resigned this in 1852, and went out into the world to seek his fortune He became editor of the *Mechanics' Magazine* and soon began to play an active part in literary and scientific circles One of his greatest services to the cause of naval science was rendered in connection with the foundation of the Institution of Naval Architects in January, 1860 This would hardly have been practicable, at that time, but for the devotion and ability with which Mr Reed performed the onerous duties of honorary secretary during the period of organisation, and those of secretary for three years after

Mr E J Reed was appointed Chief Constructor of the Navy in July, 1863 This appointment followed upon proposals he had made some time before for improving the design of ironclad ships The earliest ironclads of the *Warrior, Minotaur*, and other classes were found to be imperfect and unsatisfactory, and Mr Reed proposed a radical change of design by limiting the armoured portion of the hull to what was merely sufficient for the proper protection of its vital parts—such as the compartments containing the boilers, machinery and magazines, the gun battery, the rudder head and steering gear, and the waterline area before and abaft the gun battery This became famous as the "belt and battery" system and it is, in principle, the system adopted in the design of battleships and armoured cruisers to-day It enables the thickness of armour to be increased to a maximum upon a given size of ship, and admits of the application of thick armour to ships of smaller dimensions than would otherwise be requisite The wooden ships *Enterprise, Favourite* and *Research* were ordered by the Admiralty to be converted in accordance with Mr Reed's proposals in 1862, and the design of the *Bellerophon* followed immediately after he took office in 1863 The last-named was the first of a continually progressive series of historical ships that led in direct line to the last of our armourclads which fought their guns upon the broadside, while the *Devastation*, the last battleship designed at the Admiralty by Sir Edward Reed, is the first in the series of sea-going battleships, the heaviest guns of which are placed in turrets on deck, which now reaches its latest development in the *Dreadnought* In these typical designs the lines which future progress in battleship design would take are clearly indicated The design of the structure of the hull in the *Bellerophon* was novel and ingenious It has been followed in all subsequent battleships and cruisers for the British Navy, and adopted all over the world An important factor in Mr Reed's success at the Admiralty, which the writer frequently heard him mention, was that he had as his principal assistants Messrs Barnaby (his successor for fifteen years as Chief Constructor of the Navy), Barnes, and Crossland, the best of his old fellow-students at the Portsmouth school He always said that without the aid of men of the highest scientific and technical training, as they were his achievements would have been impossible The value of their

scientific knowledge and ab n naval construction that
new and difficult problems nting themselves for solu-
were then continually preseurnish one of the strongest
tion was so manifest as to fuiralty of the necessity of
proofs to the Board of Admool of naval architecture
maintaining an efficient schof detailed reference to

Space will not admit Admiralty during the

was also naval architect for Crown Colonies, and
and the Government of theps of various classes for
designed many successful ship
those Governments

Sir Edward Reed was a strenuous advocate, as we
have said, of scientific and tecchnical education The
School of Naval Construction at Portsmouth, at which
he was educated, was abolished by the Admiralty in
1853, but he joined with other leading members of
the Institution of Naval Architects in 1863 to urge
upon the Admiralty the necessity for establishing
another school for the scientific training of young
naval architects and marine engineers for the
Admiralty service, and also for the mercantile ship-
yards of the country This action resulted in the
foundation of the Royal School of Naval Architecture
and Marine Engineering at South Kensington in
1864 to which most of the leading naval architects
and marine engineers of to-day owe their scientific
training Mr Reed, as Chief Constructor of the
Navy, never failed to promote the interests of this
school He was one of its best and most popular
lecturers, and those who passed through the school
at that time owe to him their first appointments to
responsible posts, in which their qualities could be
tested, and their early professional advancement

In 1873 Sir Edward (then Mr E J) Reed contested un-
successfully the Borough of H a Parliamentary
election He was returned the Pembroke
Boroughs in 1874 and for C in 1880, and sat
continuously in the House of Commons from 1874 to
1895, and from 1900 until last , when he retired
from Parliamentary life He made a C B in
1868 and K C B. in 1880, and ed as member, and
sometimes as chairman, of ny important com-
mittees He was chairman of the Load-line Com-
mittee of 1884 which first made legislation for regu-
lating the depth of loading of ships successful in
practice, and of the Manning of Ships Committee of
1894 He was also the Goverrment Commissioner

who investigated the cause of capsizing of the *Daphne* in the Clyde in 1883. Sir Edward was one of the Lords of the Treasury in Mr. Gladstone's Government of 1886.

Sir Edward Reed was elected F.R.S. in 1876. He sat upon the council of the Institution of Naval Architects from 1863, when he retired from the secretaryship, until his death, and upon the council of the Institution of Civil Engineers from 1883 to 1896. He was the recipient of very high Russian, Austrian, Japanese, and Turkish honours and decorations. Among the works published by him are:—"Shipbuilding in Iron and Steel," 1869, "Our Iron-clad Ships," 1870, "Letters from Russia in 1873," "Japan," 1880, "The Stability of Ships," 1884, "Modern Ships of War" (in collaboration with Admiral Simpson), 1885, "Fort Minster, M.P.," a novel, 1885; "Corona and other Poems," 1857, and "Poems," 1902. He was also the author of numerous papers in the Transactions of the Institution of Naval Architects and other professional institutions, and of two important papers, "On the Relation of Form and Dimensions to Weight and Material in the Construction of Ironclad Ships," which were communicated to the Royal Society by the late Sir George Stokes, and are published in the Philosophical Transactions of 1868 and 1871. He was also the proprietor and editor of the quarterly magazine *Naval Science* from 1872 to 1875, and contributed many articles to its pages.

The subject of this imperfect memoir was not merely a great naval architect, but a man richly endowed by nature with many and varied gifts. He was cheerful and sanguine in disposition, with an attractive and impressive personality, and unusual force and independence of character. He was lucid, graceful, and fluent of speech, and one of the ablest and most effective speakers and controversialists of his time. He long commanded public attention as man of science, politician, orator, and author, and in the last-named capacity he had the unique distinction of earning laurels in fields so far removed from those of his severe professional labours as poetry and romance. No one was more popular or more genuinely admired among his professional brethren and children for his great abilities and accomplishments, and his genial and sociable nature, than the late Sir Edward Reed. FRANCIS ELGAR.

NOTES

A REUTER message from Stockholm states that the formal distribution of the Nobel prizes took place on Monday evening. Prof. Moissan, Prof. Thomson, Prof. Golgi, and Prof. Ramon y Cajal each received the prize diploma and a gold medal from the King of Sweden in person. Each prize this year amounts to 7659*l.* Prof. Thomson's prize is awarded to him for his researches extending over many years into the nature of electricity, and Prof. Moissan's for his experiments in the isolation of fluorine, his researches regarding the nature of that element, and for the application of the electric furnace to the service of science. Profs. Ramon y Cajal and Golgi are bracketed for the medicine prize on account of their works dealing with the anatomy of the nervous system.

THE Government geologist of South Australia reports that the discovery of corundum in the Farina district is likely to be one of considerable value. The corundum occurs in metamorphic schist, the proportion in the rock amounting in places to 10 per cent. to 25 per cent.

THE American mail brings the announcement of the death, on November 23, of Dr. William H. Chandler, emeritus professor of chemistry at Lehigh University, at the age of sixty-five years. Dr. Chandler taught for many years in the Columbia School of Mines, and was the author of several important works.

IN an article in the *Pall Mall Gazette* (December 10) with the somewhat sensational title of "The Approaching Conquest of Cancer," Dr. Saleeby states that several cases of cancer have been cured or much improved by injections of trypsin, one of the pancreatic ferments, a method of treatment suggested by Dr. Beard, of Edinburgh. Even if this be correct, however, it by no means follows that cancer is to be conquered in the near future, and the premature publication of such details as these in the public Press serves no useful purpose.

MR. W. R. BUTTENSHAW, who has been scientific assistant on the staff of the Imperial Department of Agriculture for the West Indies during the last four years, has been offered the post of botanist in the Agricultural Department of India. He will vacate his present post as soon as his successor has been appointed.

THE annual conversazione and exhibition of new apparatus arranged by the British Electrotherapeutic Society will be held in the small Queen's Hall on Friday, December 14, from 7.30 p.m. to 10.30 p.m. The exhibition will be open from mid-day.

WE learn from the *Chemist and Druggist* that a wealthy landed proprietor named M. Audrac, who died recently at Le Luc, near Draguignan, has left the Pasteur Institute the whole of his fortune, valued at the equivalent of 50,000*l.* at least. Interviewed on the subject, Dr. Roux, the distinguished director of the institute, stated that he had received a visit from a lawyer, who informed him that a will had been found bequeathing the whole of the property to the institute. The reserve, however, was made that another document might possibly come to light making various bequests or otherwise disposing of part or whole of the property; consequently Dr. Roux says that some time must elapse before the Pasteur Institute can know definitely how it stands with regard to the inheritance.

BY the death of Mr. John Ward, of Longton, Staffs, British geology has lost one of those quiet, earnest workers who, in the midst of their other duties, achieve so much for science. Mr. Ward was an original member of the North Staffordshire Field Club, and one of the most regular and valued contributors to its Transactions. In 1874 he was elected a Fellow of the Geological Society of London, and in 1898 he was the recipient of an award for his work upon the fossil fauna and flora of the North Staffordshire Coalfield. As a collector, Mr. Ward was the happy possessor of a splendid enthusiasm tempered with sound knowledge; a large part of his collection of Coal-measure fishes is now in the British Museum (Natural History). While attending to the conduct of his business and devoting his spare time to geology, Mr. Ward yet found it possible to take a prominent part in the duties of citizenship. He will be missed greatly by students of Carboniferous faunas, not in this country alone, but by his numerous friends abroad.

THE following telegram, dated Bombay, November 20, has appeared in the public Press:—"Dr. von Lecoq, a scientific emissary of the Prussian Government, has arrived safely at Srinagar after a journey through the most remote parts of Central Asia. He has brought with him a quantity of highly interesting paintings on stucco, the backgrounds in many cases being of gold leaf as in Italian

work, and a number of manuscripts in ten different languages and one wholly unknown tongue. Dr. Lecoq's discoveries probably constitute the greatest archæological find since the days of Layard and Rawlinson." Dr. von Lecoq will probably not be over-pleased with the last sentence of this telegram, for the wording of which he of course is not responsible. He had been sent to explore sites in Chinese Turkestan like those discovered by Dr. Stein some years ago; Dr. Stein published his discoveries in his well-known book "Sand-buried Cities of Khotan" (reviewed in NATURE of July 21, 1904, vol. lxx., p. 275). Dr. von Lecoq has evidently trodden successfully in Dr. Stein's footsteps, and has, judging by the description in this telegram, found antiquities of the same type as those brought back by the earlier explorer, and now exhibited in the British Museum. To compare with the epoch-making discoveries of Rawlinson and Layard the work even of the pioneer of the archæology of Turkestan, Dr. Stein, would show great want of a sense of proportion. Such comparisons are always odious, and often, as in this particular instance, simply silly.

THE eighteenth annual dinner of the Institution of Electrical Engineers was held on December 4. The president, Dr. R. T. Glazebrook, F.R.S., presided over a distinguished company. Mr. H. Babington Smith, who proposed the toast of "The Institution of Electrical Engineers," pointed out the good which has been done by the visit of foreign friends in the summer, one of the results of which was the establishment of the International Commission for the Standardisation of Electrical Nomenclature and the Rating of Electrical Machinery under the auspices of the Institution of Electrical Engineers. The recent growth of wireless telegraphy was then compared with that of what might be called ordinary telegraphy. In 1825 a telegraph line was laid for a distance of about eight miles, and this might be regarded as the starting point of ordinary telegraphy. Little advance was made during the next ten years, and it was more than forty years before telegraphy across the Atlantic became practicable. Wireless telegraphy, on the other hand, was put into practical application in less than ten years from its beginnings, and the crossing of the Atlantic will probably be satisfactorily accomplished in less than forty years. The president, in replying, referred to the tablet recently unveiled by Lord Kelvin in memory of Michael Faraday in the building (formerly a chapel in which Faraday worshipped) of the National Telephone Company at Barnsbury, London, N. It is seventy-five years since Faraday first published a description of his original magneto-electric machine. Progress has indeed been great since then, especially during the last few years. The basis upon which the subject rests has been firmly established by Faraday's disciples, Kelvin, Maxwell, and others, and the progress has been great because the efforts of scientific and practical men have been combined in due proportions. Lord Justice Buckley proposed "Science and Industries." Sir Arthur Rucker, in responding, said that science and industry are mutually supplementary. The general view, no doubt, is that industry follows rather from science, and the corresponding view is that science follows from industry. There is an element of truth in both views. Very frequently, indeed, great scientific discoveries follow from the efforts of those who are interested in industry. The two things are best closely combined.

IN No. 1496 of the Proceedings of the U.S. National Museum (vol. xxxi., pp. 569–591) Mr. M. Ward Lyon points out that the great anteater inhabiting Central America, for which he proposes the name *Myrmecophaga centralis*, is readily distinguishable from the typical *M. tridactyla* (or *jubata*) of Brazil by skull-characters. As shown in the plate accompanying his paper, the most distinctive difference between the skulls of the two forms is to be found in the degree to which the frontals interpenetrate the nasals, the dissimilarity in this respect being very great. It was only to be expected that detailed examination would reveal local differences in a type ranging from Guatemala to Brazil.

No. 1495 (vol. xxxi., pp. 539–568) of the Proceedings of the U.S. National Museum is devoted to a detailed description, by Mr. A. Hrdlička, of a collection of twenty-six skulls of the orang-utan obtained by Dr. Abbott in western Borneo, twenty-four of these coming from the Sakaiam River district in Landak. Some difficulty was experienced in determining which specimens belonged to fully adult animals, the dentition affording no trustworthy evidence. The best test, in the case of males, appears to be the fusion of the temporal ridges to form a sagittal crest. After recording measurements of a number of the specimens, the author refers to various dental abnormalities, such as the presence of supernumerary cheek-teeth and the diminution in the size of the hinder molars in some female specimens.

Two papers in the *American Anthropologist* (vol. viii., No. 2, April–June), the one by Dr. J. C. Merriam and the other by Prof. F. W. Putnam (to whom we are indebted for separate copies of both), deal with recent cave-exploration in California, and the evidence thereby afforded in favour of the existence of Pleistocene man in that State. The mammalian fauna of Mercer's, Potter Creek, and Samwel Caves (which appear to be the most important of the group) has been described in various papers by Messrs. E. L. Furlong and W. J. Sinclair, who have recorded remains of the ground-sloth Megalonyx and of two remarkable new genera of ruminants, Preptoceras and Euceratherium, which seem to show evidence of affinity both with the musk-ox and with the Himalayan and Tibetan takin (Budorcas). In some of these caves it appears to have been the custom of the natives to throw in the bodies of their deceased relatives, and the bones remaining from these appear to be younger than those of the ground-sloth fauna. The most important evidence of the coexistence of man with the latter is afforded by certain polished and pointed bones, a small percentage of which are perforated. Many of these bones recall those found in the shell-mounds, although they are less rough, and some may be portions of Euceratherium skeletons. Stone-payments showing unmistakable evidence of man's handiwork occur in the caves, and in Prof. Putnam's opinion these are probably of Pleistocene age. According to the same authority, two perforated bones figured in his paper "are sufficiently important to warrant the belief that man inhabited the vicinity of the caves at least as early as the latter part of the Quaternary period."

PROF. KELLOGG, of the Stanford University, gives in *Science* of November 23 a short account of a preliminary investigation conducted by Miss L. Ramsay under his direction as to assortative mating, in nature, between individuals of different varieties of the lady-bird *Hippodamia convergens*. The investigation was interrupted by the great earthquake, but from sixty cases noted it is concluded that the matings are "wholly non-selective, they are chance matings." This conclusion is not, however, quite in accordance with the numbers given in the text,

which, so far as they go, indicate a certain degree of homogamy, and it is to be hoped that the investigation will be taken up again next year with the view of obtaining sufficient observations to warrant a more confident conclusion

A PRELIMINARY notice of the Ramie Growing Association, formed with the object of fostering the industry in this fibre, has been received from the honorary secretary, Mr D Edwards-Radclyffe

THE list of seeds of hardy herbaceous plants and of trees and shrubs available from Kew for exchange with botanic gardens has been published as the first appendix to the *Kew Bulletin* for 1907

IN view of the fact that there is an import trade of sugar into India exceeding a quarter of a million of tons per annum, it is difficult to realise that nearly one-fifth of the world's output of sugar is produced in the Indian Empire chiefly from the sugar-cane and also from certain palms In the course of an article on the subject in *Tropical Life* (November) the annual production in India is roughly computed at three million tons, and if more efficient methods of extraction were adopted this amount could be largely increased Among various references to rubber in the journal, a note on block rubber indicates the advantages attending this method of preparation over the previously belauded biscuit, and an article on Ceara rubber refers to the hopeful expectations of establishing the tree in various parts of southern India A short account of Mr W Fawcett's efficient work in Jamaica accompanies his photograph that is presented in this number

A FLORA of the State of Washington, prepared by Mr C V Piper, forms vol xi of the Contributions from the United States National Herbarium Partly owing to the seaboard position of the State, the flora presents numerous ecological features of interest that are described at some length and lavishly illustrated Six important zones are distinguished, the upper Sonoran area coextensive with the sagebrush, *Artemisia tridentata*, the humid transition where the red fir, *Pseudotsuga mucronata*, is dominant the arid transition area characterised by prairies of *Agropyron spicatum* or forests of *Pinus ponderosa*, a Canadian zone where *Pinus monticola* grows, a Hudsonian or zone of *Abies lasiocarpa*, and an Alpine region The systematic enumeration shows a preponderance of Compositæ, in which order Senecio is an important genus, among other large orders, Castilleja, belonging to the Scrophulariaceæ, Lupinus and Phaca, to the Leguminosæ, are characterised by a considerable proportion of endemic species

THE current issue of the Records of the Geological Survey of India (vol xxxiv, part ii) contains the statistics of the mineral production of India during 1905, by Mr T D La Touche The total value is given as 5,707,956*l*, which is 350,116*l* in excess of that for 1904 Nearly every item shows an increase Gold, with a value of 2,416,966*l* takes the first place, and coal, with a value of 1,436,951*l*, the second The output of coal, 8,417,739 tons, has again exceeded all previous records Other minerals for which returns of production are given are, in order of importance, petroleum, salt, saltpetre, manganese ore, mica, rubies, jadestone, graphite, iron ore, tin ore, chromite, diamonds, magnesite, and amber Incomplete returns are given for alum, arsenic ore bauxite, borax, building stone, clay, copper ore, cornelian, corundum, garnet, gypsum, limestone, marble, slate, steatite, and tourmaline In the same issue Mr F Vredenburg gives a detailed account of *Nummulites Douvillei*, an undescribed species from Kachh, named in honour of the geologist whose researches on the Foraminifera have thrown so much light on the classification of the Tertiary system The paper concludes with a summary of the zonal distribution of Indian Nummulites Mr J Malcolm Maclaren gives a detailed description of some auriferous tracts in southern India, in territory under British administration or within the Nizam's dominions The paper is accompanied by a coloured geological map of the Gadag auriferous belt, Dharwar district In this goldfield the extensive old workings are of great interest Numerous small vertical shafts, 4 feet square, were sunk by the ancient workers to the dip of the veins, often not cutting the vein until the shafts were 80 feet in depth The veins were then followed on the underlie with great assiduity to a depth of at least 300 feet Abundant relics of mills for crushing quartz exist Those of most frequent occurrence were essentially rock breakers, in which the quartz was broken to the size of a walnut They are depressions 6 inches wide and 4 inches deep in hard rock Into these mortars there fitted rude stone pestles 9 inches long, and sufficiently thick to be grasped in the hand The Gadag goldfield is exceptionally well situated for economic working, and is of special geological interest in the occurrence of its gold-quartz veins in argillites In the last paper Mr R R Simpson records the abandonment of the collieries worked by the Government of India at Warora, Central Provinces, in consequence of a serious subsidence that took place on March 28

Ancient Rock Mortars, with Pestles, near Sangli Mines, Gadag

FATHER GUTIÉRREZ LANZA S J, assistant director of the Belén Observatory, Havana writes taking exception to the statement in these Notes, in NATURE of October 25 (vol lxxiv, p 642), that the great hurricane of October 17 had burst over Cuba "apparently with little or no warning" The note was based on the cabled reports which stated that Father Laurent Gangoiti had telephoned to Columbia Camp an hour before the storm burst announcing its

approach From the information now supplied by Father Gutiérrez-Lanza, it is clear that both in the local newspapers and in messages to the U S Weather Bureau at Washington, Father Gangoiti had on October 12 announced the existence of a cyclonic disturbance south of Barbados, on October 16 that it was about 500 miles south of Havana at 6 a m October 17, that it was approaching western Cuba and moving towards Florida, and at 3 p m of the same day that the cyclone was nearing Havana province The storm reached the city of Havana at 10 p m The word "apparently" in the note was intended to cover any possible imperfections in the hurried early reports of the calamity With the information bearing upon the predictions of the approach of the recent hurricane towards Havana, Father Gutiérrez-Lanza has forwarded an interesting brochure on "The Pioneer Forecasters of Hurricanes" by the Rev Walter M Drum, S J, of Georgetown University

IN *Engineering* (vol lxxxii, No 2135, December 1) Mr H Burcharts gives illustrations of the sand-blast apparatus used for testing building materials at Gross-Lichterfelde Institute Some results of tests are given showing that the new method gives useful information with regard to the power of resistance to wear in practical use, and to the quality of road and floor materials The duration of the exposure to the sand blast has, after many experiments, been fixed at two minutes, the steam-gauge indicating a pressure of two atmospheres This short time suffices to give a good indication of the structure of the materials tested and their resisting qualities The sand used is a natural quartz sand of fine and nearly round grains, procured by washing and drying the original sand and passing it through a sieve with 120 meshes per square centimetre, or about 774 meshes per square inch It is the waste from the German standard sand used for testing Portland cement the grains of which pass the sieve of sixty meshes, and are retained on the sieve with 120 meshes per square inch Granite from Malmo lost 0 09 cub cm per square cm, blast-furnace slag Bochum, 0 12 red pine 0 10, and linoleum 0 02.

SIGNOR GUIDO BORDONI-UFFREDUZZI gives a summary of sanitary progress in Milan, accompanied by diagrams of statistics of death-rates, particularly from infectious diseases, during the past thirty years The paper is published in the Lombardy *Rendiconti*, xxxix, 14

PROF TEMISTOCLE CALZECCHI-ONESTI, writing in the *Rendiconti* of the Lombardy Institution, xxxix, 14, regarding the discovery of the coherer, directs attention to his experiments made in 1884, before Branly had worked on the subject He further points out the important part played by Righi in the discovery of wireless telegraphy

IN the *American Journal of Mathematics*, xxviii, 3, Mr F J B Cordeira discusses the analogy between gyroscopes and cyclones The author considers that the oscillations of a gyroscope have a close analogy in the motions of cyclones about a position of equilibrium It is also suggested that the frictional couple due to cyclones tends to accelerate the earth's rotation, and that the effect is cumulative, though it should be noticed that the only possible result is the transference of angular momentum between the atmosphere and earth, and that the total angular momentum of both cannot be altered

IN the Proceedings of the Royal Philosophical Society of Glasgow, under the title "Solution of Physical Problems," Prof Andrew Gray, F R S, discusses two problems in the theory of attractions The first is the determination of the attractive force between the two halves of a sphere of gravitating matter, the surfaces of equal density being concentric spheres The problem for the case of uniform density was solved by Prof Tait in a very simple way by considering the hydrostatic pressure on the supposition that the sphere was fluid In the present paper three methods are considered, namely, the hydrostatic method, a method based on Gauss's well-known theorem of the flux of force over a closed surface, and a third based on a simple theorem according to which the attraction between two concentric hemispherical shells is the same as if the mass of the inner shell were concentrated at the centre The second part of the paper consists in a re discussion of the problem of the attractions of ellipsoids, with some historical notes and alternative methods of treatment.

THE number of the Journal of the Chemical Society published on November 29 contains abstracts of several mineralogical papers One of these (F Zambonini) describes crystals of galena deposited by sublimation on the scoria at the edge of the crater formed as a result of the eruption of Vesuvius in April This galena appears to owe its origin to the action of hydrogen chloride on the vapours of lead chloride An abstract (F Hussak) describes the bean-shaped pebbles considered to be a good indication of the presence of diamonds, in the alluvial gravels at Diamantina, Brazil They include two new mineral species and consist of barium aluminium phosphate, named gorceixite strontium aluminium sulphato-phosphate, named harttite, and lead aluminium phosphate, probably identical with plumbogummite An abstract of a paper by Mr A Pauly describes a new mineral of the zeolite group from Hainburg, Lower Austria, and another (G d'Achiardi) deals with a similar mineral from Elba

MESSRS W HEFFER AND SONS, Cambridge, have purchased the mathematical library of the late Prof Joly, of Dublin, and the botanical library of the late Prof Marshall Ward, of Cambridge Catalogues of the libraries are in preparation

WE have received a copy of an important contribution to the *American Anthropologist* (vol viii, No 3, July–September), which has been published separately The paper, which was presented by the American Anthropological Association to the International Congress of Americanists held at Quebec this year, deals with recent progress in American anthropology, and is a review of the activities of institutions and individuals from 1902 to 1906

EVERY attempt to increase the number of people with an intelligent interest in science deserves encouragement Our contemporary *Knowledge and Illustrated Scientific News* continues its efforts in this direction, and presents its readers month by month with accurate and interesting accounts of modern scientific work prepared by writers in close touch with knowledge in the making In addition to illustrated articles, each issue of the magazine includes sections in which the progress made in the various branches of science is noted in correct though popular and easily understood language

THE issue of "Who's Who" for 1907 is even more complete than the edition of a year ago Its size has been increased by nearly a hundred pages, and there are now 1058 pages of short autobiographies of persons of import-

ance in the world of work and the world of society Prominence is given to men of science who have added to knowledge, and many foreign investigators are recognised equally with those of our own country There is however a striking disparity in the amount of detail provided in the various life-histories while in the case of some American scientific workers details are provided of each step in their careers and of their individual papers many Fellows of the Royal Society supply the reader with next to nothing about themselves, but as a whole "Who's Who" is an indispensable work of reference, and the editor is to be congratulated upon its completeness The tables which were formerly included with the biographies and were in fact the nucleus of the book are published separately in an extended form under the title "Who's Who Year book, 1907"

OUR ASTRONOMICAL COLUMN

COMET 1906*g* (THIELE) — A new set of elements and an ephemeris for this comet computed by Dr F Stromgren appear in No 4138 of the *Astronomische Nachrichten* The following is an extract from the ephemeris —

Ephemeris 12h M T Berlin

1906	α (true) h m	δ (true)	1906	α (true) h m	δ (true)
Dec 14	12 59	+53 6 4	Dec 26	14 35	+58 24 6
18	13 32	+55 29 2	30	15 2	+59 13 3
22	14 5	+57 12 7			

On the last named date the brightness of the comet will be about half that at the time of discovery (mag = 8 5)

The results of a number of observations of this object appear in No 4137 of the same journal

COMET 1906*h* (METCALF) —Numerous observations of this comet are recorded in No 4138 of the *Astronomische Nachrichten* and an ephemeris and set of elements calculated by Herr M Ebell are also given

Observing this object with the large equatorial of the Bordeaux Observatory on November 22 M E Esclangon perceived two nebulosities near to his comparison star B D 3° 696 These objects were easily visible and differed in shape the first being elongated, with a length of about 30″ and the second being circular with a diameter of about 20″ Taking α and δ as the equatorial coordinates of the star B D 3° 696 the coordinates of the respective centres of the nebulosities at 11h 30m (M T Bordeaux) on November 22 were

α − 6 4s δ + 6″ and α 5 3s δ 2 20″

but the various settings on the second object appeared to show an hourly movement of α = + 0 7s δ = 7″ On November 23 M Esclangon was unable to re discover these nebulosities

On receiving the news of this observation it occurred to Prof Kreutz that the nebulosities might be companions to comet 1906*h* and he therefore asked for observations of B D − 3° 696 from several other observatories Prof Millosevich replied that he could find no appendices to this star which was however unfavourably placed for observation whilst at the time of publication no other observers had been able to make the desired observations

A METEORITE IN THE ATLANTIC (OCTOBER 17) —The owners of the Prince line of steamers have received a letter published in the *Liverpool Journal of Commerce* (November 27) from Mr C B Anderson captain of the *African Prince* describing the fall of a meteorite observed by him on October 17 Captain Anderson says in the course of his letter —"On the evening of October 17 I was on the bridge with the second officer when suddenly the dark night was as light as day and an immense meteor shot comparatively slowly at first because the direction was so very perpendicular to our position then more rapidly towards the earth Its train of light was an immense broad electric-coloured band gradually turning to orange and then to the colour of molten metal When the meteor came into the denser atmosphere close to the earth it appeared, as nearly as it is possible to describe it like a molten mass of metal being poured out It entered the water with a hissing noise close to the ship"

SOME REMARKABLE SMALL NEBULÆ —In No 4136 of the *Astronomische Nachrichten* Prof Barnard describes and gives diagrams of, several remarkable groups of small nebulæ which he has discovered since 1888

In the first group there are six nebulæ two of which were probably originally discovered by Stephan in a circular field of 16′ diameter The second group also contains six two of which are remarkably small and are elongated and several other nebulæ were suspected in the same field From the frequency with which these groups occur associated in isolated compact clusters Prof Barnard thinks there can be no doubt but that the members of each group are physically connected Both the above groups and two others found in 1889 and 1890 respectively were discovered with the 12 inch refractor of the Lick Observatory

Another nebula which from its remarkable shape Prof Barnard has named the "Bug Nebula" was discovered by him with a 5 inch refractor in 1880 This object as seen in the 36 inch refractor is a triple nebula having streamers running in a north preceding direction from the two preceding components and two nebulous arches springing from the following component thus giving the whole the appearance of a ghostly beetle of some kind In the N G C it is designated by the number 6302

THE PERIOD OF β CEPHEI —Finding that the observations of the interesting spectroscopic binary β Cephei made during 1901 and 1902 were insufficient to fix the period with certainty although they showed that in all probability it was exceptionally short Prof Frost made arrangements to obtain several spectrograms on each observing night during the past summer and now publishes a preliminary account of the results in No 4 vol xxiv of the *Astrophysical Journal*

As many as twenty two prism plates with an average exposure of twenty minutes were secured in one night and the preliminary discussion of the total shows that the period of the star's radial velocity is probably very near to 4h 34m 11s The provisional measures also indicate a range of velocity of about 34 km from about + 12 km to − 22 km

Some speculations as to the radius of the orbital motion of the bright component and the inclination of the orbit to the line of sight suggest that the bright body must be near to the centre of gravity of the system and they also raise the question as to whether the two components must not be nearly in contact Indications of the second component spectrum suggest that the difference between the magnitudes of the two bodies may be small

If these preliminary measures are confirmed the period of β Cephei is by far the shortest yet discovered for a spectroscopic binary star

NEW VARIABLE STARS By the method of superimposing a negative upon a positive of the same region taken on a different date Miss Leavitt has discovered twenty eight new variable stars in the region of the Southern Cross and the Coal sack Two these were discovered on a plate having the Orion nebula at its centre and one on a plate having the Pleiades central Prof Pickering remarks on the paucity of variable stars in the vicinity of the Pleiades and states that the conditions in that region seem to favour unusual constancy in light The position and the range of variability of each of these thirty-one variables are given in Circular No of the Harvard College Observatory

OBSERVATIONS OF PHŒBE IN 1906 From Circular No 119 of the Harvard College Observatory we learn that nine additional photographs of Saturn showing images of Phœbe were obtained with the 24 inch Bruce telescope at Arequipa during August and September The photographs have been measured and the resulting positions of the satellite in respect to Saturn are given in the Circular

AMERICAN GOOSEBERRY MILDEW

MR. E. S. Salmon, the mycologist to the South-Eastern Agricultural College at Wye, Kent, is the active leader of an agitation against a mildew affecting gooseberries known as *Sphaerotheca mors uvae*. The fungus in question is of American extraction, and somehow it was introduced into Ireland about the year 1900, it has since spread, has already effected much mischief, and will undoubtedly cause more.

In Sweden it has, we believe, been very destructive, and quite recently its presence has been detected in England. Curiously enough, its introduction into Britain has been associated with the yellow-flowering currant *Ribes aureum*. This is a Californian shrub that has long been cultivated for ornamental purposes in this country, and, up to this time, we have not heard of its being subject to the attacks of mildew.

It now appears that Continental growers of gooseberries make use of *Ribes aureum* as a "stock" whereon to graft the common gooseberry. Standard gooseberries are by no means in general cultivation in this country, and we are informed that the use of *Ribes aureum* is being discontinued owing to the circumstance that it produces objectionable suckers. We do not know what object cultivators had in using *Ribes aureum* as a stock, and indeed we were not aware that it was so used until recently, but from the circumstance already mentioned that the golden flowered currant has long been cultivated here without detriment to neighbouring gooseberry bushes, we may acquit it of anything but indirect participation in the spread of the mildew.

Still in whatever way the pest may have been introduced we cannot but look upon it as a serious matter. The trade in ripe gooseberries is no doubt relatively of little importance, but the prices obtained in the market for "green gooseberries" early in the season are often very high, and the market gardener who was deprived of this source of income would suffer seriously. In face of these facts it is recommended that the importation of all gooseberry bushes, especially of those "worked on" *Ribes aureum* be prohibited and that all bushes known to be affected should forthwith be destroyed by fire.

It is evident that such measures could never be efficiently carried out by individuals. If one grower in any district proved negligent, all the careful ones would suffer from his default. No system of Government inspection would be sufficient to keep out the intruder. Not the keenest mycologist in the world could guarantee that no fungus spores were introduced even if the importation of gooseberry bushes were prohibited. Not the most experienced microscopist could guarantee that all the fungus spores in a particular plantation were destroyed by the cremation of the affected bushes. The spread of the Phylloxera throughout the vine growing countries, despite the most elaborate precautions, shows how ineffective those precautions were. At the same time they caused much inconvenience and loss to the traders and others—a loss which was all the more serious, as, except in the case of vines, it was wholly unnecessary.

It is to be hoped that if legislation on the lines proposed by Mr. Salmon be carried out it will be administered with due discretion, otherwise the remedy may prove more injurious to the interests of the cultivator than the mildew itself. In the meantime the Board of Agriculture has issued a circular giving a description of the fungus and of its mode of life directing the attention of growers to the imminence of the danger, and recommending that every precaution be taken in the purchase of the bushes, especially those from Ireland and the Continent, that all affected shrubs be forthwith burnt, and that as a measure of precaution spraying with Bordeaux mixture be carried out during the winter in the case of plants in any way open to suspicion. The Board states that there is at present no law dealing with the eradication of the pests of fruit trees, and that it depends very largely on the action of the dealers and of the growers whether or not the further development of the pest can be prevented.

*Since writing the foregoing remarks we notice in the *Times* of December 8 that Mr. Massee has, at the request of the Board of Agriculture, visited the neighbourhood of Evesham, where he was told that the disease had existed for thirty years, "and had not affected the fruit," so that there is absolutely "no necessity for panic." Panic and discretion are at opposite poles. If we might offer advice to the gooseberry growers it would be that they should practise watchfulness and act with discretion.

RECENT PROGRESS IN MAGNETO-OPTICS.[1]

Rotation of the Plane of Polarisation close to an Absorption Band.[2]

FARADAY'S rotation of the plane of polarisation is extremely small in all gases, also in sodium vapour. Only within a very narrow range close to the sodium lines the rotation is positive and very great, a fact discovered by Macaluso and Corbino.[3] In a recent extremely interesting paper Prof. Wood has given measurements of observed rotation of four complete revolutions.[4] This, however, was in rather dense vapour, at least dense in comparison with the vapour used in the experiments now to be described, in which vapour containing about one-millionth gram of sodium per c.m.[3] was used.

The magnitude of the rotation close to the sodium lines is illustrated by measurements made by Dr. Hallo in the Amsterdam laboratory. It is clear that on both sides of an absorption line the rotation is in the same direction. We may attenuate the vapour still further so that the doublet in the direction of the lines of force becomes visible. What is the rotation, then, between the components of the doublet?

It is easily deduced from Prof. Voigt's theory that in very diluted vapours the rotation must occur, in a sense, opposite to that outside the components, and therefore negatively, and also that it must be very great. In the case of sodium vapour I had the pleasure to confirm this theoretical result, and to observe rotations of $-400°$.

In these experiments interference fringes in the spectrum were used, established by means of a system of Fresnel quartz wedges (a method used by Voigt, Corbino, and others in similar cases). I will project these fringes on the screen.

If a plate of quartz, which rotates the plane of polarisation, is held in the ray, you will notice a displacement of the fringes. A plate of glass has no influence, of course. I have here a quartz plate which rotates the plane of polarisation through 90°, and you will notice a displacement of half the distance between two fringes. A displacement of the entire distance between two fringes corresponds to a rotation of half a revolution.

Analysing the light by means of a Rowland grating we can produce such a system of fringes for all wave-lengths and can consider the rotation for wave-lengths close to the controlling absorption bands. On the screen I will first project the fringes close to the sodium lines with the field off. The dark vertical lines are the sodium lines. They are broad because the vapour is rather dense. The horizontal bands are the interference fringes. With the magnetic field on, the image now projected is seen.

You see how fast the rotation increases in the vicinity of the absorption lines, becoming more than 180° closer to the bands. In the interior of the bands only a hazy fringe is seen. A remarkable equation, first deduced by Becquerel[5] gives the law of the rotation. The phenomenon is more beautiful as soon as the vapour is so thin that the doublet is seen (Fig. 5).

Outside the components of the doublet the fringe rises *upwards*, but inside the components the fringe has moved *downwards*, the rotation is negative there. The rotation is $-90°$ for D_1, nearly $-180°$ for D_2. It is very interesting to watch the movement of the fringes in the spectroscope as the field is increased or the density of the vapour changed.

Double Refraction and Resolution of the Absorption Lines

In the second place, we will now consider the *double refraction* which occurs whenever light traverses a vapour at right angles to the magnetic field. A plane wave with vibrations parallel to the field has a velocity different from that of a wave with vibrations at right angles to the field. It is only close to the absorption band that the difference becomes perceptible. Sodium vapour in a magnetic field behaves as a double refracting crystal for light close to the sodium lines. This result of Voigt's theory was verified by him in conjunction with Wiechert in the case of dense vapours, and commented upon by Becquerel and Cotton.

With great density, and using the same system of interference bands, the phenomenon assumes the appearance now projected. Whereas the rotation of the plane of polarisation was symmetrical on both sides of the absorption band, you see that the double refraction is not. On one side of the absorption line sodium vapour behaves like a positive crystal, on the other side like a negative one. With very dilute sodium vapour, and with a magnetic field strong enough to resolve the sodium lines, the theory must be extended. There is no difficulty here. The observations made by Mr. Geest, as well as by myself, concerning the details of this double refraction, have fully confirmed Voigt's theory.[1]

The slides shown always refer to *one* of the yellow sodium lines, and hence the structure seen is almost entirely confined to the extremely small region between the components of one line. The line D_2 splits up into three components in a moderate field. The theoretical course of double refraction is given in a diagram, next to it the result of observations is given (Figs. 6 and 7). On a somewhat larger scale the appearance is as now shown. With greater density the characteristic sinuous line undergoes transformation. The line D_1 splits up into a quartet. Besides the concave parts, you will now notice a line with a point of inflexion in the theoretical and in the observed curves.

The same phenomenon is again illustrated by the next slide, where also the change which occurs with greater density is manifest. In a very strong field the line D_2 is resolved into a sextet. The inverse sextet can be readily seen with the means at our disposal, but the phenomena occurring between these narrow-spaced components could only be seen with difficulty. Only in very favourable circumstances Mr. Geest observed the image now projected.

All the described phenomena are qualitatively in excellent accordance with Voigt's theory. It is certainly very interesting that the theory is able to explain the complicated course of double refraction by the difference between the velocities of propagation of vibrations at right angles and parallel to the field.

Magnetic Resolution and Intensity of Field

Let me again refer to our first subject, the magnetic separation of the lines. The magnitude of this separation is proportional to the intensity of the field in which the source is placed. We may, therefore, deduce the intensity of the field from the magnitude of the magnetic separation. We have only to measure the distance of the components of a suitable line. It is not generally known that

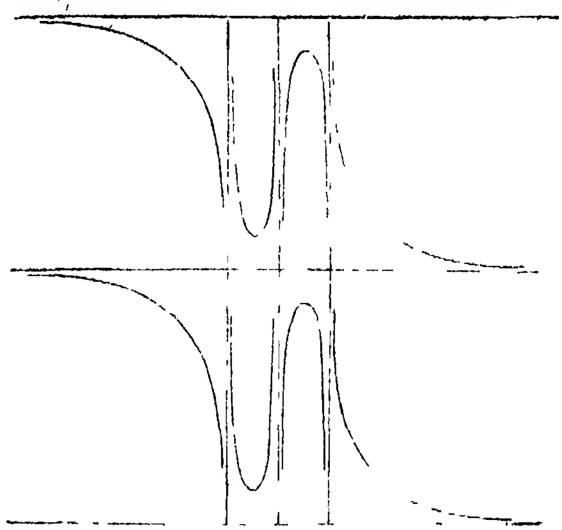

Fig. 6.

Fig. 5.

this distance can be measured with great accuracy (with an error of considerably less than 1 per cent.). It is therefore far easier, if a relatively high degree of accuracy is necessary, to compare the intensities of field by measurements of the distance between the components than by direct magnetic measurements.

All methods used for the measurement of magnetic fields give us the intensity in a point. On the other hand, the magnetic resolution of spectroscopic lines can give us the intensity *in all points belonging to a line*. Moreover, in this manner we make direct use of a property of the atom.

You see here a vacuum tube with some mercury. We heat the tube and excite it with the coil. You notice the brilliant light which is, however, greatly increased when the tube is placed in a magnetic field.[1] For a given density of the vapour there is a definite intensity of field for which the luminosity is a maximum. You can see this when we put on the current in the electromagnet, the intensity of the field then rises gradually.

We project an image of the tube on the slit of a spectroscope. This spectroscope must be so arranged that to every point of the slit there corresponds a point of the image. The blue line of mercury (4359) resolves into a sextet. Using this line, the field of a du Bois electromagnet with a pole distance of 4 mm. is mapped out in the spindle-shaped optical magnetograms now shown (Fig. 8). We may, of course, extinguish the light of the inner components. In some cases a triplet will give more accurate results. The method sketched will, of course, only be applied in difficult cases. So long as our spectroscopes of great resolving power are rather cumbersome there is no practical application for the method. By means of this method we may also study some questions as to the way in which certain phenomena which accompany the resolution depend on intensity of field.

Fig. 7.

[1] Paschen, Physik. Zeitschr. I. S. 47, 1 [illegible]

We have no time, however, to discuss this further, because I should like to refer to the important subject of the

Behaviour of the Different Lines in the Magnetic Field

In many metallic spectra a number of lines occur which are closely related, and form so-called series of lines. The important discoveries of Hartley, Liveing, and Dewar were followed by the discovery of series, owing to the indefatigable efforts of Balmer, Kayser and Runge, Rydberg and Schuster.

The plate shows diagrammatically the arrangement of the three connected series which are found in the spectra of the alkalies and other elements, and which are distinguished by Prof. Schuster[1] as the trunk series (Kayser and Runge's "Hauptserie"), the main branch series (Kayser and Runge's "Zweite Nebenserie"), and the side branch series (Kayser and Runge's "Erste Nebenserie").

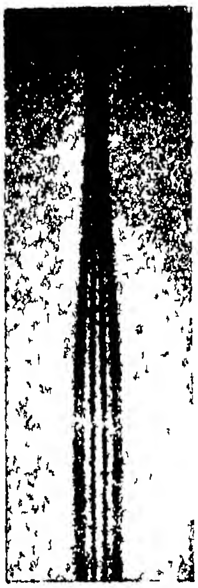

FIG. 8

The laws of these series are simpler than those governing acoustical vibrations. They are of an entirely different character, for instance, the members of each series approach some definite limit of frequency, whereas the number of acoustical vibrations may increase indefinitely.

My first measurements already made it evident that lines of different series behaved entirely unlike each other.[2] Hence the ratio of charge to mass could not be the same for all vibrating electrons.

Runge and Paschen have proved in a most beautiful and systematic investigation[3] that all the lines of a trunk or of a branch behave in the same manner. This result was first announced by Thomas Preston,[4] but it is not stated to what degree of accuracy and for how many lines he investigated the subject.

All lines of the same series are split up in the same manner, *e.g.* all lines are resolved into triplets or all into nonets. Moreover, not only the general type of subdivision is the same, but even the amount of separation when measured in oscillation frequency.

The second law discovered by these physicists is this: That corresponding series of *different* elements show the same type of resolution, and the amount of separation is the same when measured on the frequency scale.

In the alkalies each line of the trunk series is double, and we may speak of a twin trunk. The yellow sodium lines are a typical example. The type of resolution of the two lines is shown in the diagram (Fig. 9). Here we have again our old sodium lines in the field. The same division occurs in all cases when twin trunks exist.

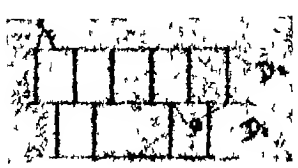

FIG. 9

Substances so different in chemical behaviour as sodium, copper, silver, and calcium (*e.g.* the well known lines H and K), split up in the same manner, and I think that even Sir William Crookes will be surprised to hear that his thallium lines are in the magnetic field only counterfeit sodium lines. I can show you the splitting up of these beautiful thallium lines in the slide.

[4] Preston, Dublin Trans. (2) 7, pp. 7–22, 1899.

With zinc, cadmium, mercury, and calcium, there are *three* main branches associated with each other. The amount of separation is the same in each of these branches. The type of resolution is shown in the diagram (Fig. 10). I can show you further lines of mercury, the triplet, the sextet, the nonet. Another example of the same sextet is given by a zinc line. The next slide refers to some beautiful magnesium lines exhibiting the same three types of resolution (Fig. 11).

We see that in these cases the simple image of an oscillating electron does not apply. I regret to say that the electronic theory cannot yet give us the explanation of the more complicated resolutions, even for the quartet we are yet in want of a model.

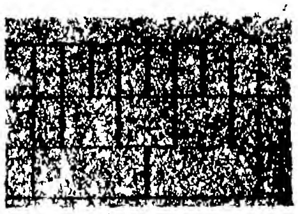

FIG. 10

The laws discovered, however, seem to point to the conclusion that all the lines of a series are emitted by one oscillating system, that there are therefore as many series in the spectrum of a substance as oscillating systems in its atom, moreover, that the oscillating mechanism is the same in different elements. We are reminded here of the view advocated by Sir Norman Lockyer that the different elements have something in common. The relation between these spectral series and resolution in the magnetic field is so close that we may expect that the solution of the problem of the series will give at the same time the solution of the magnetic separation problem.

That Lorentz's theory is on the right track, even in the case of the more complicated magnetic effects, appears from the polarisation of the nonet shown in the slide. Three groups of vibrating lines here correspond to the three lines of the triplet. The circular polarisation corresponds also

FIG. 11

to that of the doublet, indicating that it is always the negative electron which executes the vibrations. There is yet room enough for experimental work in extending these investigations in different directions and to other elements.

Much light on our present subject will be thrown undoubtedly by the activity in adjacent chapters of physics. I can only mention in this relation the extremely interesting experiments by Lenard and Stark on the centres of emission of different spectral series, and the important theoretical work by Drude[1] on the optical properties and electronic theory. Maxwell has said, "an intelligent student armed with the calculus and the spectroscope can

[1] Drude, *Annalen der Physik*, pp. 677, 936, Bd. 14, 1904.

hardly fail to discover some important fact about the interior structure of a molecule" I think this statement remains as true now as it was thirty-two years ago There can be no doubt, I think, that spectrum analysis, and especially the magnetisation of the spectral lines, will give us a clue to the inner structure of the atom I hope that I have succeeded in imparting to you this my conviction

THE ERUPTION OF VESUVIUS IN APRIL, 1906

THE most complete published account of the eruption of Vesuvius in April last is due to the enlightened liberality of the French Government, which commissioned Prof Lacroix to study and report upon the eruption, and it is gratifying to find that this, as all other detailed accounts by qualified scientific observers of the eruption of Vesuvius, confirms in every respect the description which we were able to disentangle from contemporary newspaper reports and publish in our issues of April 12 and 19 As a result of Prof Lacroix's researches he has, in addition to more detailed memoirs published or to come, communicated to the *Revue générale des Sciences* of October 30 and November 15 an interesting account of the result of his observations and deductions, some of which are sufficiently interesting to deserve notice, in extension of what we have already published

The earlier stage of the eruption was of the Strombolian type, that is to say, the material ejected from the crater was formed by the breaking up of molten lava it was consequently red hot, and Prof Mercalli, who was watching the eruption from Torre Annunziata, noticed that the mountain became covered, for from 200 metres to 300 metres from its summit, with a continuous sheet of glowing material, from which blocks incessantly rolled down to lower levels At 0h 31m and again at 2h 40m a m on April 8 violent earthquakes were felt, corresponding to the most violent paroxysms of the eruption, accompanied by a lowering of the height of the cone and a change from the Strombolian to the Vulcanian type of eruption From this time onward the ejected material was less and less composed of fresh lava, and less and less incandescent, being composed, in increasing degree, of the old solidified lavas and tuffs of the cone

For several days after April 8 the summit was hidden by a thick cloud of ashes, and when this cleared away the mountain was found to have changed its form from a pointed to a truncated cone, like that left after the eruption of 1822, though not so low or with so large a crater When it became possible to ascend the cone it was found that the new crater was a true caldera, almost circular, of 640 metres to 650 metres in diameter, surrounded by walls almost vertical, except at the top, where a steep talus reached up to the crest, and at the bottom, where a funnel shaped talus sloped down into a cloud of vapour escaping from the fumeroles The rim was irregular in height and generally sharp-crested, but cut by a deep gap on the north-east, where, for some 80 metres, the crest was not only lower, but comparatively flat-topped, this gap faces the crest of Somma in the direction of Ottajano, where scoriæ and ashes fell in quantity sufficient to crush in the roofs of houses, while the observatory, less than half as far from the crater in the opposite direction, received but a very small quantity of these same ejections Prof Lacroix rejects the explanation that this difference was solely due to wind, and considers that he has established a case of oblique eruption, the average direction of projection being not vertical, but inclined at a considerable angle towards the north-east

The greater part of the material blown out from the crater fell on the slopes of the cone, which was covered many yards deep with a loose deposit of fine dust, ashes and blocks of all sizes Even before the eruption ceased the surface of this deposit began to be broken by dry avalanches, which crashed down on every side leaving the cone deeply scored by a series of radiating valleys, separated by steep-sided, sharp-crested ridges Later on, rain-water sinking into and saturating these loose deposits set them in motion as the well-known mud lavas, the mode of flow of which resembles closely that of the molten lava, and still later the rain-water, flowing off the surface, formed torrents of more liquid mud which cut through the earlier accumulations of the dry avalanches and mud lavas

The eruption was accompanied by a change in level of the land, but this was confined to the immediate neighbourhood of the volcano, for the tide-gauge shows that there was no alteration in the relative level of land and sea at Naples, while Prof Mercalli found an elevation of from 30 cm to 48 cm between Portici and Vico Equense. Of mineralogical interest is the new mineral, of which the first published description appeared in NATURE of May 31, and the discovery of galena as an addition to the list of Vesuvian minerals

RUSSIAN OBSERVATIONS OF THE SOLAR ECLIPSE, AUGUST 30, 1905

CONSIDERING the unfavourable weather conditions experienced by many of the eclipse parties last year the members of the Russian expedition in charge of M A Hansky, are to be congratulated on the results they obtained, which have been recently circulated as a publication of the Pulkowa Observatory The observers were stationed at Alcocebre, on the Mediterranean coast near Valencia The central line of totality passed almost exactly through the station, and various local conveniences combined to render the choice of site favourable to efficient observation On August 15 all the instruments were received in good condition and after observations had been made for determining the azimuth of the sun's rising point, the various pillars and stands for the apparatus were erected

Photographs of the corona were taken on two scales - small pictures with the Bredikhine double photographic telescope furnished with a Zeiss objective of 170 mm aperture and 800 mm focal length, giving a field of 12° 4 in R A and 8° 8 in declination, large pictures, for the delineation of fine detail in the coronal streamers, with an objective of 5 inches aperture and 13 28 m focal length, the light being supplied from a cœlostat 30 cm in diameter Spectroscopic observations of the corona and prominences were made with a direct vision spectroscope without slit, and the polariscopic phenomena examined by the aid of a Savart polariscope Measurements of the solar radiation were taken with an actinometer and actinograph of Crova's pattern

Near the time of eclipse the sky became clouded over, but about a minute before totality the sun was seen in clear sky The corona was seen five or six seconds before totality, and the last ray of sunlight was visible for some two seconds probably through a deep valley in the moon's limb This feature is also shown very clearly in the photograph of the chromosphere accompanying the report which is divided up into a series of bead-like masses at that particular place Visually the corona was seen of a brilliant, silver-white colour, its brightness increasing rapidly towards the moon's limb The longest rays seen extended about one and a half lunar diameters, and were situated near the poles of the sun, one at the north and two very fine ones at the south pole The sky had a green colour, similar to that often seen about half an hour before sunrise Careful examination of the spectrum of the corona during one of the forty-seconds' exposures showed that the continuous spectrum was especially strong in the green, yellow, and red, the latter region being so brilliant that it suggested the possibility of photographing the corona in ordinary daylight by means of suitably prepared colour screens

With the polariscope the coronal light was seen to be strongly polarised and the conditions were such that the dark bands were not visible on the sky surrounding the corona The bands were much stronger when tangential to the sun's limb than when radial There appeared to be a rotation of about 2½° of the plane of polarisation which may possibly be ascribed to the action of a magnetic field round the sun

Eight photographs of the corona were obtained with the long focus telescope, the exposures varying from 40-45

seconds The longest were somewhat over-exposed near the limb, and showed structure to about three-quarters the lunar diameter Six photographs were taken with the Bredikhine coronagraph, the first of which only was successful, most of the others being much over-exposed On the good plate the star ρ Leonis was photographed, thereby giving an accurate means of orienting the plates for determining the position angles of the prominences and coronal streamers These values are tabulated for the more important streamers M Hansky considers that the results obtained confirm the idea that the corona varies, not only in form, but in brightness and spectrum, with the sun spot period During this last eclipse the brightness was probably ten times that of the full moon, while at epochs of minimum spots the corona has only been about as bright as the full moon Owing to the sky being frequently clouded over, the actinometric observations are of only small importance, but the character of the record obtained indicates that Crova's instrument is very convenient for such investigations

Shadow bands were observed before the commencement of totality the direction of their displacement on the ground being from west to east They were badly defined at their edges, but became more definite as totality approached They appeared of a brownish colour and moved with a velocity of 2–3 metres per second the motion being apparently oscillatory and not translatory Their distance apart was not more than 25 centimetres Other observations made at Amposta showed the bands to be 5–7 cm wide and 10–15 cm apart, the displacement being from north-west to south-east At the end of totality the corona disappeared immediately, and no shadow bands were seen The sunlight appeared to return suddenly, without any gradual change such as was observed before totality

CHARLES P BUTLER

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD—The following examiners have been appointed —In zoology Dr J W Jenkinson Exeter College in preliminary physics, R L Baynes, Christ Church, in preliminary chemistry H B Hartley Balliol College, in preliminary animal physiology Prof F Gotch, Magdalen College in preliminary zoology, R W T Gunther, Magdalen College in medicine, Dr A E Garrod Christ Church in organic chemistry N V Sidgwick, Lincoln College in materia medica, Dr R Stockman in anatomy, Prof A Thomson, Exeter College in physiology Dr H M Vernon Magdalen College, in pathology, Prof G Sims-Woodhead, in forensic medicine, Dr H H Littlejohn in surgery D'Arcy Power Exeter College, in obstetrics, J S Fairbairn Magdalen College

Dr J W Jenkinson, Exeter College, has been appointed lecturer in comparative and experimental embryology

T Lindsay Glasgow University, has been elected to a Brakenbury scholarship in natural science at Balliol College

An examination for a Radcliffe travelling fellowship of the annual value of 200*l*, tenable for three years will commence on February 26, 1907 Intending candidates should send their names to the regius professor of medicine by February 9

CAMBRIDGE—Mr A G Tansley assistant professor of botany at University College, London, has been appointed lecturer in botany in succession to Mr A C Seward, who has succeeded the late Prof Marshall Ward in the chair of botany

The Vice-Chancellor has published a further list of donations to the benefaction fund which has now reached a sum of 96,400*l*

Mr L G Bedford of Sidney Sussex College has been appointed assistant demonstrator at the Cavendish Laboratory to hold office from January 1, 1907 to September 30, 1911

Prof B Hopkinson has been appointed chairman of the examiners for the mechanical sciences tripos, 1907

The Arnold Gerstenberg studentship (1906) has been awarded to A E Baker, Trinity College, for an essay entitled "A Critical Examination of Descartes' Philosophy of Nature"

The special board for biology and geology has adjudged the Walsingham medal for 1906 to W E Agar, for his essay on "Researches into the Embryology of the Dipnoi," and W L Balls, for his essay entitled "Studies of Egyptian Cotton"

It is proposed that, in accordance with a recommendation of the general board of studies, a university lecturer in hygiene be appointed for a period of five years, in connection with the special board for medicine, and with an annual stipend of 100*l* payable out of the funds in the hands of the State Medicine Syndicate

The authorities of Gonville and Caius College, having decided to close their chemical laboratory at the end of the present academic year, a syndicate was appointed on November 8 to consider the assignment of a site for the extension of the chemical laboratory The conclusion arrived at is that, of the sites available, the one site which is not liable to considerable objection lies between the chemical laboratory and the new medical schools, with a frontage next Pembroke Street

The antiquarian committee recommends that it be authorised to hire an old malting house at Newnham for a period of five years in which to store some of the collections under its charge The need for a new museum of ethnology and archæology is indeed becoming pressing The University has assigned a site for such a building and a building fund has been started by Baron von Hügel curator of the museum but until that fund is very considerably augmented the University will be compelled to store away many of its treasures in a building inaccessible to students, and quite unworthy of the treasures it contains The committee also recommends that the numerous small sums which it receives from the financial board for the upkeep of the museum be consolidated and that an annual grant of 420*l* be placed at its disposal for each of the five years 1907 to 1911

THE fourth annual prize distribution of the Sir John Cass Technical Institute was held on December 4, when Sir William Ramsay, K C B, F R S delivered an address and distributed the prizes The chair was taken by Sir Owen Roberts, chairman of Sir John Cass's foundation In reviewing the work of the institute Sir William Ramsay dwelt upon the scope and aims of those who follow the study of science with the view of making discoveries whose main object is to extend the boundaries of science and to gain knowledge, in contrast with those who on the one hand, restrict their work to duties of a more mechanical character, involving less responsibility and are satisfied with the discharge of their daily task and with those, on the other, who find their work and interest in the direction and guidance of business concerns and in the control of their fellow-men The comparative rewards and the nature of the successes of these various classes of workers were contrasted and the possibilities of the Institute in training students to fill one or more of these different spheres of activity were outlined Turning to the awards made on the work of the past session Sir William Ramsay advised students not to aim at prizes, if prizes come, well and good but they should not be the object of work The chief aim, he said, should be to get on with the work in hand to do it as well as possible, even if the labour brings no immediate reward, and to seek for knowledge for the great thing in life generally is to be and not to get Previous to the distribution, Mr George Baker, chairman of the institute committee, made a short statement of the work of the institute in which he pointed out that its relation to the industries of East London is beginning to be known and appreciated by manufacturers and expressed the hope that it would in the course of time prove a real and progressive help to the trades and industries of the district

SOCIETIES AND ACADEMIES.

LONDON

Royal Society, June 28.—"The Pharmacology of Ethyl Chloride." By Dr. E. H. **Embley.**

Four years ago Dr. Embley published the result of an investigation into the pharmacology of chloroform which he had carried out in the physiological laboratory of the University of Melbourne,[1] primarily with the view of elucidating the cause of those sudden misadventures which occur in chloroform administration, and more particularly during the early period of the induction of the anæsthetic.

Dr. Embley's work, however, covered the whole subject of the physiological action of chloroform in a very thorough manner, and perhaps one of the most striking merits which it possessed was due to the fact that the experiments were conducted throughout with definitely known percentages of chloroform in the air respired.

The present work on ethyl chloride is conducted in the same quantitative manner, and with the same command of physiological technique, as shown by the excellent graphic records which illustrate the paper.

Ethyl chloride was first used as a general anæsthetic in 1848 by Heyfelder. It subsequently fell into disuse, but was revived in 1895. Its position is intermediate between nitrous oxide and chloroform or ether.

According to Embley, blood absorbs more than twice as much of the gas as water under similar conditions, so that ethyl chloride, like chloroform, evidently enters into loose chemical union with the blood.

The first point ascertained was the direct effect of ethyl chloride upon the mammalian heart.

Isolation of the heart was obtained by ligation close to the aorta of all the systemic arteries, except the subclavian. By this procedure the circulation was confined to the heart, lungs, and one limb, the nervous system being cut off from its blood supply is instantly put out of action. The pressure in this miniature circulation was recorded by a manometer connected with one carotid artery.

The effect of ethyl chloride upon heart muscle, as is the case with chloroform, and in contrast to ether, was paralytic, but the quantity of ethyl chloride vapour in the air required was nineteen times as great as that of chloroform to produce comparable results.

The direct influence of ethyl chloride upon the arterioles was demonstrated by driving an artificial circulation first through the isolated lungs and then through the isolated intestine of an animal, and measuring the outflow before, during, and after the admixture of definite percentages of ethyl chloride in the air rhythmically pumped into the lungs.

The administration of air containing 20 per cent. to 30 per cent. of ethyl chloride was found directly to paralyse the arterioles. The effect upon the vasomotor system in the intact animal was studied by taking simultaneous records of the arterial blood pressure and of the volume of various organs. These experiments showed that with 20 per cent. to 30 per cent. ethyl chloride in the air respired, a considerable degree of paralysis of the vasomotor system occurred.

Vagus inhibition of the heart was found readily to occur when above 9 per cent. of ethyl chloride vapour was present in air. Between 10 per cent. and 20 per cent. inhibition caused sudden fall of blood pressure and cessation of circulation. These effects upon the heart were due to stimuli passing down the vagi from the central nervous system, for on cutting these nerves the circulation was instantly resumed. This sudden inhibition of the heart was not, however, nearly so dangerous as the same effect easily produced by chloroform, for the direct paralytic effect of ethyl chloride upon the heart muscle is comparatively insignificant, so that in the majority of cases recovery of the circulation readily occurred if the administration were suspended.

The effect of ethyl chloride upon the respiration is also dealt with. Ethyl chloride gradually reduces the rate and extent of the respiratory movements, and if pushed in sufficient concentration will ultimately lead to their cessation. The same interdependence between respiratory activity and blood pressure was brought out, as had been shown by Leonard Hill and the author, to obtain in chloroform poisoning. Provided the circulation were maintained, it was found nearly impossible to produce cessation of respiration, but directly serious fall of blood pressure occurred, owing to inhibition of the heart, the respiration immediately became very shallow or ceased, but returned again directly the circulation recovered.

The primary danger in the administration of ethyl chloride to dogs, as in the case of chloroform, is syncope from inhibition of the heart, brought about by the stimulating action of these drugs upon the cardiac-inhibitory centre in the medulla. As it is a stimulating action, it is more prone to occur in the early stages of administration before these nerve centres are themselves narcotised by the drug.

"Refractive Indices of Water and Sea-water." By J. W. **Gifford.** Communicated by W. A. Shenstone, F.R.S.

Reference is made to previous papers (Roy. Soc. Proc., February 13, 1902, and March 3, 1904). The same special method of observation has been adopted. Measurements of the refractive index of water for twenty-six wave-lengths and of sea-water for twelve wave-lengths are contained in the paper. Those of sea-water were made for the purpose of computing an under-water lens since successfully constructed for submarine use. The measurements were made at an approximate temperature of 15° C., but were also corrected by means of temperature refraction coefficients.

The error is estimated as in no case exceeding 0.000025, and in most cases not exceeding 0.000015. The index of water for line D, reduced to 20° C. by the temperature coefficient, is 1.333032. Dufet ("Recueil de Données numériques," vol. i., p. 83) gives 1.33303 as the mean of the measurements of twenty-nine different observers for that line and temperature. The measurements were made on the goniometer used before (loc. cit.), but have been checked by critical work on a much larger instrument.

The distilled water was prepared in platinum vessels by Mr. Bousfield; the sea-water was taken five miles from shore by Lieut. J. R. G. Evans, R.N.

November 8.—"On a Compensated Micromanometer." By B. J. P. **Roberts.** Communicated by Sir John I. Thornycroft, F.R.S.

The principle of the gauge is similar to that of Sir W. Siemens's bathymeter. The instrument described consists of a U tube having the limbs connected by a tube of small bore, the motion of the fluid in this small-bore tube being rendered visible by means of an air bubble index. The sensitiveness depends on the ratio between the bores of the limbs and the connecting tube, and also partly on the nature of the fluid employed. The fluid should have a low surface tension, and the bore of the connecting tube should preferably not exceed 1.5 millimetres. The length of the bubble should be made equal to the distance between the centres of the upright limbs—the readings will then be practically unaffected by changes of level; the readings are also indifferent to vibration or similar disturbing causes. No fluid will pass the bubble provided certain precautions are observed—of these the most important is keeping the rate of movement of the bubble from exceeding certain limits. An attachment for preventing loss of fluid by evaporation is suggested in some cases.

"The Composition of Thorianite and the Relative Radio-activity of its Constituents." By Dr. E. H. **Büchner.** Communicated by Sir W. Ramsay.

Various investigations on residues from the mineral thorianite, carried out in the laboratory of Sir William Ramsay, made it desirable to analyse a large amount of this mineral, and to determine how its radio-activity is distributed over its constituents. About 24 grams were dissolved in boiling nitric acid, and left only a small residue behind, which was then fused with hydrogen potassium sulphate. The fused mass dissolved almost completely in water. The solutions obtained were then treated in the ordinary way and separated in the various groups. Pb, Cu, Sn, Sb, Fe, Al, Ur, Th, Ce, Zr, Ti, Ca, He, CO and water were quantitatively determined; the greater part of these elements are present in very small quantities.

[1] "The Causation of Death during the Administration of Chloroform" (*British Medical Journal*, April 5, 12 and 19, 1902).

The determination of the more important ones gave the following results:—PbO, 2·42 per cent.; Fe_2O_3, 3·35 per cent.; Ur_3O_8, 13·12 per cent.; ThO_2, 70·96 per cent.; Ce_2O_3, 1·96 per cent. From 1 gram of the mineral 8·2 c.c. of helium were obtained. The original mineral possesses 83·3 per cent. of the activity of standard uranium oxide. The greater part of the constituents proved to be radio-active, though some only in a very slight degree. Nearly 60 per cent. of the activity of the mineral is allied to the thorium, about 9 per cent. to the uranium. The strong activity of the iron appears to be due to the presence of Hahn's radio-thorium. The activity of several precipitates increased during the time between two measurements, while others showed a decreasing activity, which sometimes even disappeared. It may be assumed that these precipitates are so-called X-substances; one of them resembles in its chemical behaviour a platinum metal.

Zoological Society, November 13.—Mr. Howard Saunders, vice-president, in the chair.—A very young embryo of the okapi (*Okapia johnstoni*) obtained by Dr. F. David from a specimen shot in the Semliki Forest: Prof. R. **Burckhardt**. The object not being well preserved and in an early stage, it could only be stated that all the particulars ascertainable were specially ungulate in character.—Description of a new species of turbellarian obtained during Dr. W. A. Cunnington's expedition to Lake Tanganyika: F. F. **Laidlaw**.—List of a second collection of mammals made in Western Australia for Mr. W. E. Balston, with field-notes by the collector, Mr. G. C. Shortridge: Oldfield **Thomas**. This second collection was made in the Avon watershed, and consisted of about 350 specimens, of which a fine series had been presented to the National Museum by Mr. Balston. In all, forty-two species were enumerated, and of these Mr. Shortridge gave notes on the distribution and comparative rarity at the present time, such notes being of particular value in the case of a disappearing fauna like that of Australia. An appendix dealt with a small series obtained on Bernier Island, Shark's Bay, on the north-west coast of Australia.—Sixth instalment of the results of the Rudd exploration of South Africa: Oldfield **Thomas** and H. **Schwann**. This contained an account of the mammals obtained by Mr. C. H. B. Grant in the eastern Transvaal. Twenty-one species were represented in the collection, of which one was new.—The Mollusca of the Persian Gulf, Gulf of Oman, and Arabian Sea, as evidenced mainly through the collections of Mr. F. W. Townsend, 1903–5, with descriptions of new species, part ii., Pelecypoda: J. Cosmo **Melvill** and R. **Standen**. A continuation of the enumeration of the Mollusca of the above-named seas published in the Proc. Zool. Soc., vol. ii., 1901, and completing the catalogue, the total number embraced being nearly sixteen hundred species, many of these being found to be new to science. Among the Pelecypoda, Tellina holds the premier place; most orders and families are, however, represented, and the result is a very refined and varied molluscan fauna. Some interesting forms occur among the Cardiacea, while the Pectinidæ show alliance and, in some cases, specific identity with the Erythræan fauna, monographed by Dr. Sturany.

November 27.—Mr. Howard Saunders, vice-president, in the chair.—Notes on the habits of the lesser horseshoe bat, *Rhinolophus hipposiderus*: T. A. **Coward**. This bat usually occupies different retreats in summer and winter, and during the earlier period of occupation of the winter retreat sleep is not profound. The bats feed probably in the caves or retreats, and the food is at times, if not always, consumed when the animal is at rest and not on the wing. When feeding it does not—probably could not—make use of the interfemoral membrane, after the manner of the Vespertilionidæ, but, as a substitute, the interbrachial membrane is employed. These facts suggest that the hibernation of this species, and probably of other cave-haunting bats, is not really a profound winter sleep.—An account of four species of Solenidæ contained in the collections made by Mr. Cyril Crossland in Zanzibar and British East Africa in 1901–2: F. A. **Smith** and H. H. **Bloomer**.—Attempt to explain the existence of the so-called "renal-portal" system: W. **Woodland**.—The anatomy of *Centrophorus calceus*: W. **Woodland**. The author described in particular the anatomy of the alimentary tract, which differs in several respects from that of most Selachians, and, as regards the length of the bile-duct, from most vertebrates.—Mammals collected in Korea and Quelpart Island by Mr. Malcolm P. Anderson for the Duke of Bedford's exploration of Eastern Asia: Oldfield **Thomas**. The collection consisted of about 130 specimens, belonging to nine species, of which four were described as new. Quelpart Island proved to contain a very poor mammal fauna, and the only specimens obtained there were a Putorius and a Micromys, both identical with forms found on the Korean Peninsula.

Linnean Society, November 15.—Prof. A. W. Herdman, F.R.S., president, in the chair.—A series of twenty-one specimens of *Polygala amarella*, Crantz, selected to show its wide range of form under various conditions: J. **Cryer**.—The Fjærlands Fjord, Norway: H. W. **Monckton**. During the past summer the author spent a fortnight at Mundal, on the Fjærlands Fjord, and he had paid short visits to the same place in previous years. The fjord is a long arm running from the Sogne Fjord in a north-easterly direction, and snow-fields lie near the fjord on both sides, though at a considerable altitude above it. Mundal is about ninety miles from the open sea, but Fucus grows well on the rocks and foreshore, and Mytilus and Cardium flourish. The author considered, among other subjects, the question to what extent the snow-fields and glaciers of Norway can be looked upon as relics of the Glacial period.

Anthropological Institute, November 20.—Prof. W. Gowland, president, in the chair.—A visit to the Hopi Indians at Oraibi: W. **Crewdson**. The visit took place in November, 1905, when it was late to travel across the plains of Arizona; but by starting from Canyon Diablo, on the Santa Fe route, with relays of horses, the seventy miles to Oraibi was accomplished in one day. Oraibi is the most conservative of Indian towns, practically unaltered by Western civilisation, and shows examples of primitive life in our own days, several of the implements used being still of stone; the bows and arrows and boomerangs are also used for killing game. One of the most striking characteristics of the Hopi men is their marvellous power of running; for this they are trained as children by one of the chief men, who stands on one of the Mesas and sees the young men take a twenty-mile run before commencing the day's work. The necessity for this was owing to their fields being many miles distant from their homes. The result is that a Hopi will sometimes run forty miles to his fields, cultivate them, and then run home again, all within the twenty-four hours. In the house, which is built by the woman, she rules absolutely; the children take the mother's name, the men weave the garments for both themselves and their wives, and are at any time liable to be definitely turned out of their homes, possibly after a forty-mile run, by the wife who has grown tired of her husband. These Indians are intensely religious, most of their ceremonies, which often last for days, being really prayers for rain. Their pottery is interesting, being decorated to a large extent with cloud symbols, and many pieces have a break in the design to allow the spirit which is supposed to be imprisoned in the design free ingress and egress. This idea bears a curious resemblance to the idea, once prevalent in England and elsewhere, that if a circle was drawn round a witch she could not escape unless someone cut the circle for her from outside. The celebrated snake-dance, which has been so often described, takes place in August, and it is becoming more and more probable that these Indians are really acquainted with a cure for snake bite. In November, however, the dance of the year, only second to the snake-dance, and called the basket-dance, takes place. The lecturer was present at this, having previously been admitted to the Kiwa, or underground chamber, where the preparatory rites in connection with the ceremony take place.—The relative stature of the dolichocephalic, mesaticephalic, and brachycephalic inhabitants of East Yorkshire: J. R. **Mortimer**. The inhabitants are divided into two classes: those of the Neolithic and Bronze period,

and those of the Early Iron period Of those in the first class, the dolichocephals are found to have the greatest stature and the mesaticephals the smallest stature while in the second class the mesaticephals have the greatest stature and the brachycephals the shortest stature There is, therefore, no simple relation between stature and skull length. The number of skulls examined was 151

Geological Society, November 21 —Sir Archibald Geikie, Sec.R.S., president, in the chair —The Kimeridge Clay and Corallian rocks of the neighbourhood of Brill (Buckinghamshire) A. M **Davies** The paper contains two principal divisions —(1) an account of the section of Rid's Hill, Brill, (2) the rock of Studley and Arngrove, described by Phillips as an argillaceous chert, is shown to be mainly composed of the globate spicules of the tetractinellid sponge Rhaxella. Palæontological notes are given on certain species of Lamellibranchia and Annelida, chiefly from the Lower Kimeridge Clay —The skull and greater portion of the skeleton of *Goniopholis crassidens* from the Wealden Shales of Atherfield (Isle of Wight) R W **Hooley** In the late autumn of 1904, at a place locally called "Tie Pits," near Atherfield Point, a huge mass of the cliff, comprising many thousand tons of the Wealden Shales, subsided, pushing its foot across the beach until below low-water line As the sea washed away the base, the mass continued to sink, and fresh horizons were denuded In 1905 a series of heavy "ground-seas" cast up blocks of limestone and ironstone, containing crocodile bones, which were discovered on the sand between high- and low-water marks The skull came ashore in six pieces Fragments of bones and scutes were constantly picked up The specimens were derived from a horizon 80 feet to 90 feet below the top of the Wealden Shales

Entomological Society November 21 —Mr F Merrifield, president, in the chair —*Exhibitions* H W **Andrews** Specimens of *Odontomyia angulata*, Pz, from the Norfolk Broads, of which species few captures have been recorded of recent years, and *Icterica westermanni* Mg, a rare Trypetid taken in the New Forest —Dr F A **Dixey** Specimens of South African Pierinæ demonstrating that the wet-season form of *Teracolus regina* Trim is in mimetic association with an undescribed species of Belenois, intermediate between *B calypso* and *B thysa* —H and F **Campion** A male specimen of *Sympetrum vulgatum* taken in Epping Forest on September 4 last, of which species there are recorded only three other authentic British specimens —R **Adkin** A short series of *Tortrix pronubana*, Hb, including both sexes, reared from larvæ and pupæ collected from euonymus at Eastbourne in September The only previous records for the species in Britain are single male examples captured at Eastbourne and at Bognor —Dr T A **Chapman** A long series of *Coenonympha mathewi*, Tutt, from different places in the north-west corner of Spain (Galicia), and from which it was concluded that *C mathewi* is a geographical or subspecific variety of *C dorus*, and not a fully established species.—*Papers* —A permanent record of British moths in their natural attitudes of rest, and Further notes on the choice of a resting site by *Pieris rapae* A H **Hamm** —Studies of the Blattidæ R **Shelford** —Notes on the life-history of *Sesia andrenaeformis*, Lasp Hon N Charles **Rothschild** —Notes on an unusual emergence of *Chrysophanus salustius* in New Zealand H W **Simmonds**.

PARIS

Academy of Sciences, December 3 —M H Poincaré in the chair —A new and rapid method for the determination of the errors of division of a meridian circle M **Lœwy**. A continuation of previous papers on the same subject The method is modified to allow of the direct determination of the correction of the twenty standard points —The specific adjuvants of experimental parthenogenesis Yves **Delage** It has been found that the addition of certain salts to the solution usually employed in parthenogenesis (common salt, sea water, and distilled water) considerably augments the power of the latter as a parthenogenetic agent Such substances are the chlorides of manganese, cobalt, and nickel, the last-named being the most active This result is unexpected, and no satisfactory explanation has as yet been found Different eggs, even from the same ovary (of the sea-urchin), present considerable differences, differences which neither the superficial nor histological examination offer any assistance in explaining —Concerning the expedition organised for the study of sleeping sickness A **Laveran**.—Pulmonary physiological anthracosis of intestinal origin MM **Calmette, Vansteenberghe**, and **Grysez** A repetition and extension of previous experiments in answer to the objections raised by other workers on the same subject, especially Kuss and Lobstein The authors conclude, in confirmation of their previous work, that besides anthracosis of respiratory and pure mechanical origin, the existence of which they have never denied, it is necessary to admit the existence of physiological anthracosis of intestinal origin —Observations of the comet 1906*h* made with the large equatorial of the Observatory of Bordeaux Ernest **Esclangon** The observations were made on November 22 and 23 and give the apparent positions of the comet and mean positions of the comparison stars The comet appeared as a uniform nebulosity 30″ in diameter, and without apparent nucleus —Observations of the Thiele and Metcalf comets (1906*g* and 1906*h*) made at the Observatory of Algiers MM **Rambaud** and **Sy** The observations were made on November 13 14, 16, 19, and 20, the last night furnishing the best results On November 20 the comet 1906*h* appeared as an irregular nebulosity, the lustre being comparable with that of a star of the twelfth magnitude —Observation of the Metcalf comet (1906*h*) made at the Observatory of Lyons J **Guillaume**. A single observation on November 20 The comet had the appearance of a circular nebulosity of about 30″ diameter, with a central condensation and a small nucleus Its lustre was about the eleventh magnitude —Certain transcendental numbers Edmond **Maillet**.—The critical points of inverse functions A **Hurwitz**.—Periodic functions P **Cousin** - The diffusion of solutions of copper sulphate in gelatin M **Yegounow** Copper sulphate appears to enter into combination with gelatin, but its movement rigorously follows Stefan's law —Potential equalisers M **Moulin** The combustion of filter paper impregnated with quantities of lead nitrate varying from 2 per cent to 5 per cent according to the conditions of wind, has given accurate results The use of flames or radium salts requiring many precautions has been found less practical —Researches on gravitation N **Crémieu** —A theoretical explanation of the magneto-optic phenomena observed in a crystal Jean **Becquerel** —An apparatus for compensating the inertia of selenium A **Korn** A device for overcoming the inertia of the selenium cell in telephotography —Positive charge at a distance in an electric field under the influence of ultra-violet light Mme **Baudeuf** —The reduction of oxide of chromium by boron Binet **du Jassonneix** The reduction of oxide of chromium by boron in magnesia crucibles at the temperature of the electric furnace gives ingots attackable by hydrofluoric, hydrochloric and sulphuric acids These may contain from 5 per cent to 17 per cent of combined boron If boron is present in higher proportions it exists as the carbide of boron The boride CrB constitutes the limit of saturation of chromium by boron —An extremely sensitive method for the precipitation of zinc Gabriel **Bertrand** and Maurice **Javillier** The method is based on the production of a crystallised insoluble calcium zincate Quantitative determinations of zinc can be made in this way in solutions containing only two parts of zinc in a million Even at ten times this dilution the zinc can be qualitatively detected with certainty —Nitriles and carbamines P **Lemoult** Determinations of the heats of combustion and formation of methyl and ethyl carbamines From thermochemical data hydrocyanic acid is considered to be a carbamine and not a nitrile —The action of reagents on ethyl glyoxylate L J **Simon** and G **Chavanne**. The ethyl glyoxylate was prepared by the electrolysis of ethyl oxalate, and its reaction with phenylhydrazine, hydroxylamine, and semicarbazide studied —The esterification of arsenious anhydride by alcohols and phenol V **Auger** A limited amount of alkyl ester is produced by heating together arsenious anhydride and the anhydrous alcohol If the experiment is arranged so that the water produced in the reaction is removed (with

calcium carbide), a good yield of the arsenite is produced The physical properties of propyl, normal butyl, and isobutyl arsenites are given —The orthosubstituted azo-acids and their transformation into *c*-oxyindazylic derivatives P **Freundler** —The condensation of oxalacetic ester with cyanacetic ester in presence of piperidine Ch **Schmitt** The condensation can take place in two ways, giving rise to isomeric substances possessing different properties —The replacement of hydroxyl of some carbinols by the radical $-CH_2CO_2H$ R **Fosse.**—The constitution of hordenine E **Léger.** The regulated oxidation of acetyl-hordenine with potassium permanganate gives acetyl para-oxybenzoic acid This fixes the orientation of the hydroxyl group in hordenine which is thus found to be para-oxyphenylethyldimethylamine —The volcanic rocks of the peninsula of Cape Verde (Senegal) Jean **Chautard** —The presence of galena amongst the minerals produced by the fumerolles of the last eruption of Vesuvius Ferruccio **Zambonini** Referring to a recent paper by M Lacroix on this subject, the author mentions that he contributed a paper on the same subject to the Accademia dei Lincei in August last —The intracellular inclusions of the leaf of *Rhamnus cathartica* Wladimir **Tichomirow** —The evolution of the metachromatic corpuscles of seeds during germination J **Beauverie** —The histological modifications produced in the flowers of *Teucrium Chamaedrys* and of *Teucrium montanum* by the larvæ of Copium C **Houard** —The coral formations of the island of San-Thome, Gulf of Guinea Ch **Gravier** —A respiratory calorimetric room M **Letulle** and Mlle **Pompilian.** A diagram is given of the apparatus which allows of simultaneously measuring the respiratory exchanges and heat evolved by a man over a long period The heat is determined by reading the inlet and outlet temperatures of a measured flow of water, the regulation of the temperature of the calorimeter being made automatically at any desired point between 12° C and 24° C The apparatus was standardised electrically with a possible error of 0 5 per cent —The *rôle* of the chromotropic phenomena in the study of biological and psychophysiological problems Romuald **Minkiewicz** The prophylaxy of glandular cancer of the prostate A **Guépin** —The production in medicine of static effects by high frequency resonators H **Guilleminot**

TWO HISTORIES OF CHEMISTRY

A History of Chemistry from Earliest Times to the Present Day. By Ernst von Meyer. Translated by George McGowan. Third English edition, translated from the third German edition with various additions and alterations. Pp. xxvii+691. (London: Macmillan and Co., Ltd.) Price 17s. net.

A History of Chemistry. By F. P. Armitage. Pp. xx+266. (London: Longmans, Green and Co., 1906.) Price 6s.

PROF. OSTWALD, who has done so much for the historical side of the literature of chemistry, has declared that "there is no more effective means of vivifying and deepening the study of a science than to saturate one's-self in its history." And perhaps of no science can this be more emphatically said than of chemistry. The story of its rise and development is one of the most astonishing and most deeply interesting chapters in the history of human progress. No one science can show such a splendid succession of material triumphs or afford a more striking exemplification of the truth and wisdom of Bacon's aphorism that *Scientia est potentia*. It matters little that the desire to know may have had its origin in the lowest motives of self-interest. No doubt at all times in the history of the world there have been persons curious to know for the mere sake of knowing—persons, indeed, who deliberately preferred the risk of the possible unhappiness of wisdom to the apparently certain bliss of ignorance; but such persons have always been in a vast minority. But in the main the springs of human activity—intellectual no less than physical—have their origin in an enlightened self-interest. However "pure" a science may be to its votaries, there is a good deal of human nature in it after all, and when we come down to ultimate causes it is precisely this aspect of the matter that gives to the history of chemistry its strong human interest, and makes the personal story of its cultivators so fascinating.

Teachers of chemistry do wisely, therefore, in encouraging their pupils to make themselves familiar with the main outlines of the origin and growth of their science, and since it is impossible to separate this development from the human element which underlies it, to seek also to know something of the personal history and attributes of the men who have combined to make chemistry what it is. Luckily they have not far to seek for historical compilations worthy to be recommended for such a purpose. Practically every nation that zealously cultivates chemistry has furnished its contribution to the general stock of such compilations in obedience to, or in anticipation of, a demand which from the very nature of the case is inevitable. To a large extent the several histories may be said to reflect the popular estimation of the science in the countries which produced them. The monumental work of Kopp made its appearance at the period of, and possibly in consequence of, the national movement which originated with Liebig; and Hofer's "Histoire de la Chimie" was in like manner the probable outcome of the activity in France which had its rise with Lavoisier. No original systematic work of the same character, certainly none of commensurate importance, has been put together by any English historian. Certain of our larger manuals contain by way of introduction some historical account of the origin and development of the science, and a few monographs or biographies of the better known British chemists have appeared from time to time, but as regards systematic works we are dependent upon translations of foreign treatises.

Chief among these is the work of Ernst von Meyer, which made its first appearance in 1888, and of which an English translation by Dr. McGowan was published in 1891. The volume before us is the third English edition. It has been prepared from the third German edition, published in 1905, and, thanks to the various additions and alterations which Dr. McGowan has introduced with the sanction of the author, the history is, as the phrase goes, thoroughly up to date. The main divisions of the work remain very much as before, but some of the sections have been recast and much new matter has been added and old matter altered. For example, the author has not failed to take note of the results of recent inquiries into the life and work of that most remarkable man Paracelsus, who, as the researches of Mook, Schubert, Sudhoff, Aberle, and Strunz agree in showing, was by no means the bombastic charlatan he is commonly supposed to be. The mystery of Basil Valentine is submitted to a new examination, but the conclusion does not materially differ from that already arrived at by Kopp. But it is mainly in its account of the recent development of the science that the book differs from the works of Kopp and Hofer. Kopp, in his "Entwickelung der Chemie in der neueren Zeit," only carried his history down to the beginning of the last third of the nineteenth century, a time we can no longer consider new—and the generation that has followed has witnessed an astonishing expansion both in fundamental facts and in important and far-reaching dogmas, and it is in this period that the student of to-day probably finds his chief interest. Dr. von Meyer has himself lived through it, and he writes with a full and accurate knowledge of its achievements, and in the spirit of detachment, of impartiality and insight which characterise the true historian. The work is a perfect treasure-house in its wealth of bibliographical and biographical detail. Its literary charm lies in the simplicity and directness of its style, characteristics which Dr. McGowan has well preserved in his admirable rendering into English. We commend the work to all students of chemistry in the certain conviction that they will rise from its perusal with their interest in the science—to use Ostwald's words again—vivified and deepened.

The work of Mr Armitage is of a different order, and, to the extent that it is original, is, we regret to say, a very immature production It shows few traces of independent inquiry, but is obviously based in large measure on that of von Meyer, and in general treatment follows that work pretty closely Now and again, however, Mr Armitage seeks to be original rather in mode of expression than in the compilation of facts, but he only succeeds in being obscure, and his attempts at epigram and "fine writing" usually end in bathos What, for example, is the precise meaning and value of the statement, "Even during that stage of transition which separated him from the brute creation, man must have appreciated the beneficial or harmful effect of many naturally occurring substances"? Quite true, no doubt, but the brute creation itself with equal certainty had this degree of appreciation of what was beneficial or harmful But Mr Armitage argues that in this appreciation we had the dawn of chemistry! What, too, is meant by saying that "Aristotle maintained the four elements earth air, fire and water" Of the philosopher's stone it is said, "But it was not till later that its full powers, transmuting and medicinal, obtained recognition" Considering that the philosopher's stone was a myth, could its full powers ever obtain recognition? Again, "the sulphurous smell observed on the calcination of tin was very cogent evidence of the presence of sulphur" Is it quite certain that there is a sulphurous odour when tin is calcined? What too is meant by saying, "Hoffmann's attitude was not, however, maintained by any attempt at practical verification and was moreover, devoid of the unifying intent of Stahl"? Of Priestley and Cavendish it is said, "Their outward circumstances were as diverse as their inner consciousness" This is said of Lavoisier —"The way of progress had been groped for long, the times were ripe for its discovery and Lavoisier was then chosen agent"

We further read of Lavoisier —"Complete success had awarded his efforts, and the weapons he had forged, of homage to experimental fact and scepticism of so-called established truths, were become the common property of scientific men"

Of Vauquelin we read —"His work on the separation of the rare metals platinum, palladium, rhodium iridium and osmium shows us how far the horizon had receded" The horizon must have receded very far indeed if it included indium in the time of Vauquelin It has hitherto been supposed that indium was not discovered until 1863

With respect to the attitude of Berzelius towards Dalton's hypothesis we read —"Berzelius, in reviewing the whole subject, became oppressed with the unscientific slapdash manner in which it has been approached by his contemporaries" This is precisely the feeling with which we review Mr Armitage's book, on reading it we too are oppressed with the unscientific slapdash manner in which the author has approached the whole subject of the history of chemistry

MONASTICISM.

Essays upon the History of Meaux Abbey and Some Principles of Mediaeval Land Tenure Based upon a Consideration of the Latin Chronicles of Meaux (A D 1150–1400) By Rev A Earle Pp 192 (Hull and London Brown and Sons, Ltd, 1906)

THE author of this volume is, we apprehend, a curate of Nafferton-with-Wansford, in Yorkshire, who, having obtained an exhibition at St John's College, Cambridge, for ecclesiastical history, has not neglected the subject in which he obtained distinction We welcome all such additions to the skeleton army of genuine students of antiquity, but Mr Earle has his spurs to win and his authority to establish, for it is not to be assumed that he learnt much about monastic chartularies and chronicles at Cambridge We make this preliminary remark because Mr Earle has not fortified his observations by marginal references to authority, he has written no preface, and has supplied no index We presume these essays are intended for his neighbours, and are the result of notes for lectures on the subject of an interesting abbey to the chapter of which the author's church belonged

The book is in two parts, the former containing eight chapters on the origin of the abbey and its influence on the surrounding country as imagined by the author, the latter containing six chapters on principles of land tenure The essays are stated to be based on "a consideration of the Latin Chronicles of Meaux, 1150–1400 and in the margins are placed dates which are references to volume and page of the Chronicles as published by the Record Office" We presume the Master of the Rolls' series is meant Having ascertained the scheme of the book we sought for a preface, in order to learn whether the author made an independent study of the chronicles and whether the observations and reasoning are his own But there is no preface, and we are thus unable to satisfy a reasonable curiosity The fact is that the Master of the Rolls published the chronicles of Melsa, or Meaux, in three large octavo volumes, 1866–8, the editor being Edward Bond, keeper of the manuscripts in the British Museum, and to each volume Mr Bond contributed a long and very learned preface Mr Earle ought surely to have explained whether his interesting narrative is or is not entirely derived from Mr Bond In the absence of such explanation we must presume that it is, and we regard the volume before us as an excellent abstract of three long treatises by a learned author We have, after much consideration, concluded that Mr Earle's work, easy of perusal and rather colloquial in style, presents a fairly accurate picture of human society in Holderness, as affected by one of many great institutions, religious in their origin, but commercial in practice

The abbey was founded by William le Gros, Earl of Albemarle, Lord of Holderness, in the year 1150, as the condition of being released from a vow to make a pilgrimage to Jerusalem The monk who influenced the earl was Adam, of the Cistercian Abbey of Fountains, who had much to do with the foundation of that

great house, and he obtained the Papal dispensation vacating the vow from Eugenius III, then living in France, according to this chronicle.

The abbey being established and possessed of a fair estate—the original wooden buildings replaced by stone—Mr. Earle attempts to describe the state of the surrounding country and inhabitants. Although he occasionally uses a doubtful expression, such as "the rich riding in carriages," his description seems to us good. But when the relations of the rich and poor are summarised in such words as the poor man "could not resist the Lord in the Lord's own Manor Court," the impression is produced that the author has made little study of ancient courts. The appalling results of the Black Death are well indicated, and the more this terrible period is examined the more exalted do the monks, nuns, and priests of England appear.

The essays on mediæval land tenure contain much debatable matter, and many statements which, without reference to authority, we cannot accept, as, for example, that the right to "common of pasture" could be alienated.

We have not space to discuss such questions, and must limit our concluding remarks to the fifth chapter. Here Mr. Earle states his views on the nature of bondmen, and cites the curious case of Adam, son of Ivo Grise, drawing the inference that the descendants of a bondman could at any distance of time be claimed by the heirs of the original lord. The facts stated are hardly sufficient to support so large an inference, but it certainly does seem that when the abbey acquired land from a "nativus" or his son it was thought desirable to complete the title by purchasing the claim of the lord.

It is not, of course, possible to treat with perfect accuracy an antiquarian subject within the limits of a small volume of less than two hundred pages, but we can commend Mr. Earle's essays to the general public, as they are well written with proper sympathy with an old order now for ever passed away.

THE PLANTS OF KUMAON.

Catalogue of the Plants of Kumaon and of the Adjacent Portions of Garhwal and Tibet. By Lieut.-General Sir Richard Strachey, G.C.S.I., &c., revised and supplemented by J. F. Duthie. Pp. vii+271. (London: Lovell Reeve and Co., Ltd., 1906.)

THIS catalogue is based on the collections made between the years 1846 and 1849, in the province of Kumaon and the adjoining parts of Garhwal and Tibet by Lieut. (now Sir Richard) Strachey and Mr. J. E. Winterbottom. The collection was principally made along a line extending through the province of Kumaon across the Himalaya in a south-westerly to north-easterly direction, over a distance of eighty or ninety miles from the plain of Rohilkhand at about 1000 feet above sea-level, to the Tibetan plateau at an altitude of 14,000 feet to 15,000 feet on the upper course of the River Sutlej. The collection, generally known as the Strachey and Winterbottom Herbarium, included more than 2000 species, and sets of the plants were presented more than fifty years ago to the important herbaria in this country and abroad, together with a provisional catalogue. The present catalogue includes, besides the species represented in the original Strachey and Winterbottom herbarium, the results of previous and subsequent botanical exploration of the area from the time of Wallich, Royle, Falconer, Thomson, and others, up to a comparatively recent period. Among the more important recent contributions to our knowledge of the Kumaon flora are the large collection made by the late Colonel Anderson, chiefly in the vicinity of Naini Tal, and the results of the extensive botanical explorations made by Mr. Duthie during his term of residence as Government botanist in the North-West Provinces.

Including a small number of cryptogams, the flora of Kumaon, as represented in the catalogue, contains 3043 species, representing 1084 genera. No fungi or algæ are included, and only fifty genera of lichens, hence much remains to be done to give an adequate idea of the flora so far as cellular cryptogams are concerned. On the other hand, we may regard the representation of the flowering plants as fairly complete. Mr. Duthie makes a comparison with the flora of China on the one hand and of Britain on the other. Of the 137 natural orders of flowering plants represented in Kumaon, 134 are found in China and 84 in Britain; of the 983 Kumaon genera, 812 occur in China and 287 in Britain, and of the 2073 Kumaon species, 1070 are Chinese and 226 British. The most predominant order in the area concerned, as estimated by number of species, is Gramineæ (226 species), followed by Compositæ (211 species), Leguminosæ (204 species), and Orchideæ (161 species). In the Eastern Himalaya and in British India as a whole Orchideæ occupy the first place, with Gramineæ and Leguminosæ taking the second and third and third and second places respectively in the two areas concerned, while Compositæ stands fourth in the Eastern Himalayas, and seventh in the whole of British India. For the whole world Compositæ stands first, Leguminosæ second, Orchideæ third, and Gramineæ fifth.

The arrangement of the orders, genera, and species of the flowering plants is in accordance with that adopted in the "Flora of British India." The ferns were named and arranged by the late Mr. C. W. Hope, and the Bryophyta by Mr. C. H. Wright, following the plan adopted by Mr. Mitten in 1859. The method of the catalogue is a tabular one; for each species or variety, there are indicated in a series of parallel columns the habit of growth, colour of flower, time of flowering, locality, elevation, and occurrence respectively in the Himalayas (rainy or dry), Tibet, China and Britain. The book as a whole forms a remarkably clear and concise review of the flora of an eminently interesting district of the Western Himalayas. A useful appendix is given in the form of a list comprising the determinations of the numbers in the Strachey and Winterbottom Herbarium according to the original catalogue and their equivalents in the present volume. Some of the changes are due to alterations of nomenclature, others to a more thorough investigation of the plants.

A. B. R.

ENGINEERING DESIGN AND DRAWING

(1) *Machine Design* By Prof Albert W Smith and G H Marx Pp viii+369 (New York John Wiley and Sons, London Chapman and Hall, Ltd, 1905) Price 12s 6d net

(2) *Elements of Mechanical Drawing* By A A Titsworth Pp v+130 (New York John Wiley and Sons, London Chapman and Hall Ltd, 1906) Price 5s 6d net

(1) THE authors of this text book have wisely departed somewhat from the usual practice followed in books on machine design, and have devoted the first five chapters to discussions of the general principles of kinematics which underlie the design of all classes of machinery These chapters, in fact, deal with subjects such as constrainment of motion, relative motion, linkages, linear and angular velocity diagrams &c, which the student usually finds only fully and clearly discussed in such works as Kennedy's "Mechanics of Machinery" In the sixth chapter the question of the proportions of machine parts as dictated by stress is taken up, and rules are given for the working stresses which must be adopted under any given set of conditions

Fastenings, including rivets and bolts and nuts are then considered The authors rightly point out that the dimensions of the rivets which would be necessary in order to secure a joint of absolutely uniform strength are, in the case of lap joints, usually too large for practical convenience, and that, therefore, a compromise has to be effected, but surely the tables on pp 94 and 95 are carried to an excess as regards thickness of plates as no one would in practice think of using such joints for plates one inch or more in thickness In dealing with bolts and nuts naturally only the United States standard threads are employed and in this chapter the results of some interesting experiments on the design of bolts for shock are given, it was shown that bolts with a hole drilled out in the centre through the unscrewed part so as to give them a uniform cross sectional area from end to end were much stronger against shock than the original solid bolts

The design of axles and shafts and of their bearings, including the modern ball and roller bearings, is very fully treated in several chapters, and then follow details of the design of couplings both permanent and frictional, and a complete explanation of the theory of the transmission of power by belts and of the necessary calculations in order to settle the dimensions of belt required in any given case

Fly-wheels and toothed wheel gearing are taken up in the next two chapters, the proper shape of gear teeth and their strength being dealt with in a very thorough manner In the concluding chapter a branch of machine design usually much neglected in text-books is discussed, namely, the proportions and best shapes for machine frames

The authors are to be congratulated on the fact that they have avoided crowding their illustrations with minute details, and, as a result, all the figures are clear, and the important points in the design which they are intended to illustrate are easily followed The book should prove a useful text-book for engineering students in their first and second years' courses in machine design

(2) This book is divided into two parts In the first part, for beginners the various drawing instruments in common use are described, and a series of exercises is given to illustrate the use of each of the instruments The rest of this section is devoted to examples in simple projection, to intersections of solids, and development of surfaces Part ii, for more advanced students comprises problems in descriptive geometry, isometric projection oblique projection, shadows and perspective work, and concludes with a series of problems The author has dealt with a branch of engineering drawing which is more commonly denoted by the name of geometrical drawing The volume will form a useful text-book for students in engineering colleges during the first year of their course

T H B

OUR BOOK SHELF

Das Kloster Kumbum in Tibet By Wilhelm Filchner Pp xi+164, with maps, plans and numerous plates (Berlin S Mittler und Sohn, 1906) Price 8 marks

ONE of the most popular fanes of Lamaist pilgrimage is the great golden roofed temple of Kumbum, about half-way between Lhasa and Pekin in the neighbourhood of the Koko Nor Lake, on the border of Mongolia It marks the sacred spot where was born in 1356 A D the reforming Lama and canonised saint Tsong Khapa who founded the now predominant yellow cap sect which wields the temporal power On the sacred spot itself within the precincts of the temple, stands an old tree which is believed to have sprung miraculously from one of the saint's hairs It is locally known as the "white sandalwood tree" and both its leaves and bark are held in great veneration as exhibiting on their surface images of the holy man M Huc, in his lively description of his visit to this sanctuary and his interview with its "Living Buddha," half a century ago, declared that he himself saw the images on the leaves, and he attributed this extraordinary phenomenon to the devilry of the priests Since Huc's time the place has been many times visited and described by Europeans lying as it does within that portion of eastern Tibet which has been annexed by China and thus much more easily accessible than the "Forbidden Land" of the Lhasa Lamas

By far the best and fullest of these descriptions has hitherto been that by Mr Rockhill the present United States Ambassador at Pekin Mr Rockhill found that the alleged images on the leaves and bark were a delusion, and that they only appeared to those votaries who had firm belief whilst the faithless could distinguish nothing extraordinary on them The specimens of the leaves and bark collected by Mr Rockhill were identified by Mr Hemsley, of Kew, as those of *Syringa villosa* Vahl, whilst Dr Kanitz, of St Petersburg, made the tree out to be ***Ligustrina amurensis*** (NATURE, April, 1896, pp 534 and 556) Lieut Filchner now gives us a handsome monograph on Kumbum, its temple, tree, and priests, as the result of his expedition there in 1903–1905, by way of Shanghai Mr Filchner started commendably equipped with an intimate knowledge of the literature of his subject, and has produced a record of permanent value, embodying a good deal of new re

search about the temple and its large monastery of nearly 4000 priests. He devotes several pages to the sacred tree, which has been identified for him as *Syringa Giraldiana*, K. Schneider. A word of praise is due for the excellent illustrations, many of them from photographs by Frau Filchner, who accompanied her husband in his travels. Altogether the book forms a complete guide to the place, and is admirably produced at such a marvellously cheap price as is only possible on the Continent. I. A. WADDELL.

A Century's Progress in Astronomy. By Hector Macpherson, jun. Pp. xi+246. (London: W. Blackwood and Sons, 1906.) Price 6s. net.

IN attempting to crowd an account of a century's progress in one of the most progressive of sciences (during the last century) into 238 pages of well-displayed print we fear that Mr. Macpherson has attempted too much in too little space. The volume will certainly be found useful for reference as an astronomical "Who's Who," but we fear that the general reader will have but a hazy idea of the true meaning of the century's progress after perusing it.

The first two chapters, occupying more than one-sixth of the total reading matter, deal with Herschel the "pioneer" and "discoverer," and are full of interest and information. The subsequent chapters (iii. to ix.) treat of the celestial bodies in the conventional order, and as completely as can be expected in so confined a space the more important discoveries, e.g. those by Schwabe, Janssen, Lockyer, Fuchini and others concerning the sun, receiving a fair amount of attention.

The concluding chapters (x. to xiv.) deal with the spectroscopic and variable-star work, stellar systems, stellar distribution, and celestial evolution, the various theories and researches in each branch being passed in rapid review.

Speaking generally, Mr. Macpherson's information is up to date, and includes most of the events in the century's work, but in some few cases this is not so. For example, we are surprised to find that although the names of some dozen foreign double-star observers are given (p. 201) no English name has been found worthy of inclusion, not even that of Thomas Lewis. Again we believe that Sir Norman Lockyer's later researches have, by a natural order of progress, advanced his temperature classification beyond the stage where the Sirian stars were thought to illustrate the acme of temperature. A bibliography giving references to the original works so briefly epitomised in this volume would be of great value, but the book contains no references. W. J. R.

The World's Calendar. Invented by the Rev. J. P. Wiles. (London: G. Philip and Son.) Price 2s. net.

MR. WILES has devised a very ingenious toy which will exhibit the day of the week corresponding to any calendar date, and also Easter-day for any year.

We do not think that any better mechanical method could have been constructed, but we are not much in sympathy with contriving any device of the kind. The information given is not often required by most of us, and those who do require it had far better work from a concise tabular statement.

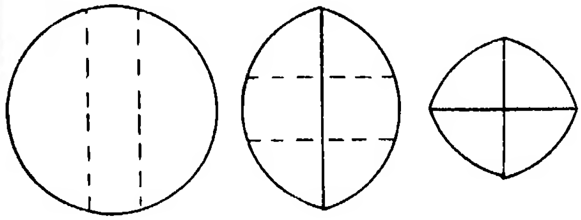
As a Christmas present it would probably give satisfaction. Perhaps Mr. Wiles contemplated this in bringing his calendar out in November. From this point of view it deserves success, and will prompt the curiosity of some to try thoroughly to understand the construction.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Cutting a Round Cake on Scientific Principles.

CHRISTMAS suggests cakes, and these the wish on my part to describe a method of cutting them that I have recently devised to my own amusement and satisfaction. The problem to be solved was, "given a round tea-cake of some 5 inches across, and two persons of moderate appetite to eat it, in what way should it be cut so as to leave a minimum of exposed surface to become dry?" The ordinary method of cutting out a wedge is very faulty in this respect. The results to be aimed at are so to cut the cake that the remaining portions shall fit together. Consequently the chords (or the arcs) of the circumferences



Broken straight lines show intended cut. Ordinary straight lines show the cuts that have been made. The segments are kept in apposition by a common elastic band that encloses the whole. In the above figures about one third of the area of the original disc is removed by each of the two successive operations.

of these portions must be equal. The direction of the first two vertical planes of section is unimportant; they may be parallel, as in the first figure, or they may enclose a wedge. The cuts shown on the figures represent those made with the intention of letting the cake last for three days, each successive operation having removed about one third of the area of the original disc. A common india-rubber band embraces the whole and keeps its segments together. F. G.

Anode Rays.

IN the *Deutsch. Phys. Gesell.* (Verh. 8, 21, pp. 559–566, November 15) there appears a paper by Gehrcke and Reichenheim under the title of "Anode Rays."

By means of a special construction a discharge is sent through a tube in which the anode consists of an inorganic salt placed on platinum foil and heated to a dull red heat by an auxiliary current. The salts used are mostly chlorides. In these circumstances a brilliant bundle of coloured rays is emitted by the anode, but this emission soon ceases. These rays the authors call "anode rays." Their positive charge is demonstrated by shooting them into a Faraday cylinder and by their magnetic deflection. These results appear to me to be attributable to the emission of positive ions by heated salts, which has already been investigated by Mr. Garrett and myself (*Phil. Mag.*, October, 1904). Mr. Garrett has continued the work described there, and finds that most haloid salts behave in a similar manner, and that this positive emission can readily be detected at ordinary temperatures. Both the number and velocity of the ions increase rapidly as the temperature is raised or pressure lowered, and in the paper mentioned we found that the emission ceased when the heating was continued. Allowing for the difference in temperature, Gehrcke and Reichenheim's results and ours appear to be different aspects of the same phenomenon. We are now seeking to determine what exactly the positive ions are, and in this connection the observation is of interest that the anode rays give very sharp lines of the metal involved when coupled with J. Stark's discovery that the canal rays are the emitters of the hydrogen line spectrum. R. S. WILLOWS.

Cass Institute, E.C., December 17.

THE DEVELOPMENT OF MODERN ARTILLERY AND EXPLOSIVES[1]

THIS volume is a re-publication of the many valuable papers and lectures which Sir Andrew Noble has contributed on the subject of artillery and explosives. Everyone recognises that there is no greater authority on these subjects than the author, and certainly the marvellous development of heavy weapons within the last forty years would have been impossible but for the solid scientific foundations which Noble and his colleagues laid down. His has been a career of activity almost unequalled, his investigations extending from the period when he was secretary to the first Committee on Rifled Cannon (1858) down to the present time, when Sir Andrew Noble still serves on the Ordnance Research Board, and only last year contributed further valuable papers on the combustion of certain smokeless powders.

As illustrating the development in gun construction which has taken place during this period, it may be mentioned that the heaviest gun in use when Sir Andrew first joined the service was a cast-iron weapon weighing 95 cwt. and firing a round shot of 68 lb. weight with a muzzle velocity of 1600 feet per second. A comparison of this with the enormous velocities, energy and range of modern weapons such as form the heavy armament of our present-day battleships clearly shows that these advances could only have been made as the result of careful scientific experiment. Noble, together with his colleague the late Sir Frederick Abel, will ever be associated as the leading minds in this magnificent experimental work.

The apology which the author makes for this re-publication is therefore quite unnecessary, and all interested in the subject will gladly welcome this volume, for the papers and lectures were delivered before such various societies that it is often difficult to obtain access to the whole of them. Necessarily there arises a certain amount of repetition, but, as pointed out, the elimination of this would practically have meant re-writing the work, so that the papers appear precisely in their original form. Not only will the collection of them prove of value to the technical man, but several will appeal to the general reader, notably those on "The Rise and Progress of Rifled Naval Artillery" and "Mechanical Science in Relation to the Naval and Military Services."

The preface alone is most interesting, and might well be quoted at length. Two points only, however, which throw light on the objection to any change in the old days, may be noted. After the introduction of rifled artillery, a dinner was given by the Royal Artillery mess to the late Lord Armstrong. After eulogising the work done by the guest of the evening, the president concluded with the emphatic statement, "for myself I am radically opposed to any change." Again later, when Artillery officers were pressing for the introduction of a naval gun weighing seven tons, the naval officers "doubted whether so heavy a gun could be carried on board ship," and a compromise was effected by introducing a gun of 6½ tons. Yet we have had vessels, the *Sans Pareil* and *Benbow* (both long since obsolete), carrying two 110-ton guns!

[1] "Artillery and Explosives." By Sir Andrew Noble, Bart., K.C.B., F.R.S., &c. Pp. xvi+548. (London: John Murray, 1906.) Price 21s. net.

The first paper deals with the "Application of the Theory of Probabilities to Artillery Practice," and afforded valuable information as to the superiority of rifled ordnance. The paper is a mathematical one based on actual firing results, the object being to determine "for each gun, that area within which, if a given number of shots were fired, half of the number might be expected to fall." This paper is followed by one on "Experiments with Navez's Electroballistic Apparatus." Other papers of similar type are those "On the Ratio between the Forces tending to produce Translation and Rotation in the Bores of Rifled Guns" and "On the Pressures required to give Rotation to Rifled Projectiles," in which the relative behaviour with uniform and parabolic rifling is critically examined.

To the man of science, as distinct from the artillerist, undoubtedly the researches on the changes taking place during combustion of explosives, the measurement of temperatures, pressures, and velocities will be of the greatest interest. These researches may be said to commence with a paper "On the Tension of Fired Gunpowder" (1871), although part i. of the now classical "Researches on Explosives" did not appear until 1875. As already mentioned, only last year a

EXPLOSION VESSEL

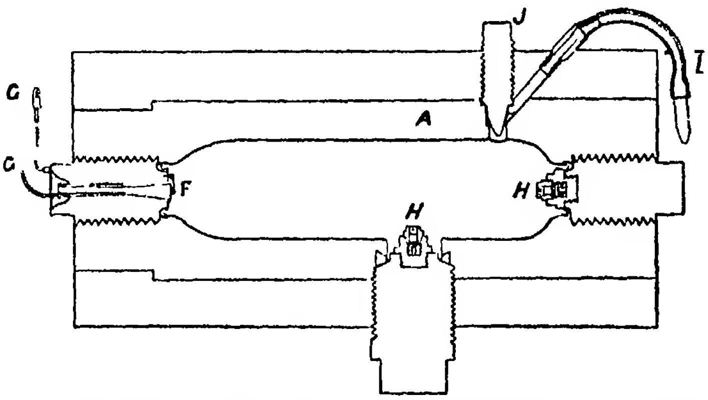


FIG. 1.—Vessel employed for small charges, to enable the gaseous products to be collected and examined. The firing plug is shown at I; the crusher gauges for determining the pressure at H, H; the escape valve for the gases at J.

further contribution under this title was published in the Proceedings of the Royal Society (followed later by a note making certain corrections on temperature estimations), which greatly extended our knowledge on the variation in the products, temperature, &c., when certain modern smokeless powders are fired under varying conditions. It is one of the few points on which we may offer criticism that these two papers are not included in the present volume, and unless some restrictions as to re-publication prevented, it is difficult to understand why they were omitted, for they are certainly not the least valuable of the series.

When Noble and Abel first took up the examination of gunpowder, the knowledge on the subject was simply chaotic. Owing to faulty methods, unjustifiable assumptions, and other causes, the most diverse ideas as to the pressure and temperature developed on firing were held. Rodman, with his well-known "cutter gauge," had done valuable work, but here, as shown in an early paper in this volume, error arose from inertia of the cutter employed. For the examination of the products on firing charges occupying but a small portion of the space in the experi-

mental vessel had been employed Sir Andrew Noble and his colleagues fully appreciated the necessity of examining the products when the powder was fired as nearly as possible under like conditions to those existing in the gun, and it was not until they succeeded in retaining all the products when the charge was fired in a space which it completely filled that knowledge on the changes commenced to have any claim to scientific accuracy Charges so large as 23 lb of gunpowder and 5 lb of guncotton have been fired in the author s explosion vessels, illustrations of which we reproduce

We have become familiar with combustions under these conditions, but it is not difficult to appreciate the risks and troubles incidental to such work, and the patience required by the pioneers to overcome these difficulties Interesting references will be found to some of these troubles in more than one paper An account of one singular accident may be quoted --

' The end of the vessel was placed against a wrought iron beam The screw- a half-inch pitch being a very good fit was screwed into its place with much difficulty and with the use of a good deal of oil On firing, the screw unscrewed until the last two threads were reached These were sheared Owing to the wrought-iron beam there was no motion of translation, but the motion of rotation was so high, that the screw first striking the ground and then an iron plate at an angle of 45°, went vertically into the air with a singular humming noise, descending in about 30 seconds a few feet from the place whence it rose "

Only two points need be mentioned in connection with the researches on gunpowder The author adopting and relying on Bunsen and Schischkoff's method for estimating hyposulphites in the residues regarded potassium hyposulphite as being formed as a primary product during combustion, a conclusion questioned by Berthelot, who regarded it "entirely as a product formed during the collection and analytical treatment of the solid residue " In a controversy which followed Noble made out a good case for supposing no change to have been possible during the preparation of the material but appears not to have considered the other possibility, faulty analytical methods Later Debus showed that this was the case and that actually the treatment produced hyposulphite, which necessitated a re-calculation of the composition of the residues Attention might have been directed to this earlier in the book

No practical method is available for determining the actual temperature of explosion but making certain justifiable assumptions, calculated temperatures of approximate accuracy may be obtained With Service gunpowder the author concluded the temperature to be about 2200° C , and regarded the signs of fusion of pieces of platinum in the charge as confirming this, Deville's value of "nearly 2000° C " being taken as the melting point of platinum Holborn and Wein have more recently shown the melting point to be close to 1780° C , so that possibly the temperatures for gunpowder are somewhat high

It may be noted that as a direct result of the researches on gunpowder, guns were constructed which advanced the velocities from 1600 to 2100 feet per second

Although gunpowder held its own for centuries with but slight modification, it has now become a thing of the past as a military propellant explosive The advantages of a smokeless powder are so great that as soon as the difficulty of "taming" guncotton had been overcome, its adoption, either gelatinised alone or mixed with nitroglycerin quickly followed Again Noble and Abel were pioneers in our knowledge of the conditions attending the use of smokeless powders Naturally the very full and lucid accounts of the large number of experiments made by Sir Andrew Noble and his colleagues will prove of even greater interest than the earlier work on gunpowder Throughout they enjoyed enviable facilities for actual trials in large experimental guns with full charges and so were enabled to correlate the values in practice with laboratory experiments

EXPLOSION VESSEL

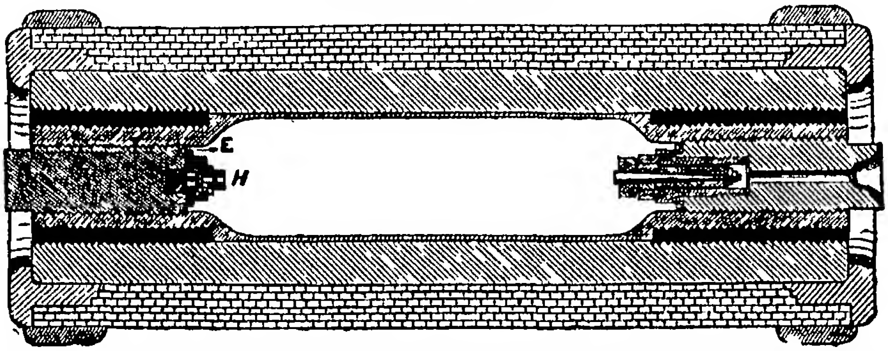

FIG 2 —Vessel employed for heavy charges Crusher gauge is shown at H the firing plug being situated at the opposite end The shell proper was strengthened by being wound with steel tape

The changes involved during the combustion of smokeless explosives are less complicated than with gunpowder Conditions, however, greatly modify the proportions in which the various permanent gases are found hence the total gas volume is also affected The influence of increasing amounts of nitroglycerin to nitrocellulose in cordites was first fully worked out by Noble and has proved of the greatest practical value since it has a close connection with the important question of erosion With the introduction of the old form of cordite for large guns, the loss of accuracy and short life of the gun became serious matters for consideration Noble showed erosion to be due to two causes, (*a*) high temperature of the products, (*b*) the motion of these hot gases Further, a series of elaborate experiments with specially prepared cordites containing increasing percentages of nitroglycerin showed that increase of temperature went hand in hand with increase of nitroglycerin, and consequently also the erosion

The logical step therefore, was to reduce the percentage of nitroglycerin and, as is now common knowledge the new M D cordite contains only 30 per cent of nitroglycerin instead of 58 per cent as in the earlier form Powder of this composition will for the same charge and size of cord, give less energy in the gun, but this may be overcome by suitable modification of the charge and size of cord These points are all made beautifully clear by some excellent coloured plates in the last paper which was delivered in 1900 at the Royal Institution Other instructive plates in the same paper are those dealing with velocities and pressures derived from them in

a series of experiments with numerous modern smokeless powders, carried out in a 100-calibre 6-inch gun

We still employ M D cordite in spite of the almost universal adoption by our European neighbours and the Americans of simple nitrocellulose powders, which they experience considerable trouble in keeping in a stable condition, and we may therefore assume that no great advance has been made since Noble's experiments clearly indicated the right path to be followed in the production of a trustworthy smokeless powder which shall give minimum erosion, whilst possessing the essential quality of stability

I S S B

A HALF-DOZEN ILLUSTRATED NATURE BOOKS[1]

If the lover of natural history and country life whose tastes incline to the study of the higher animals and who may also possess an appetite for a spice of philosophy, cannot find matter to his liking in at least one of this excellent half dozen of popular books he must indeed be hard to please The first five are charming examples of the modern style of nature-study and popular natural history works, and the general excellence of the style of the text is only equalled (or shall we say surpassed?) by the exquisite illustrations Since each volume has a special line of its own we are fortunately spared the invidious task of deciding as to their comparative merits

The first volume in the list the forerunner apparently, of a series of volumes written on the same general lines is a natural history of mammals, in which while the group is taken in systematic order, the method of treatment is so popular (and at the same time so accurate) that it can scarcely fail to appeal to a very large series of readers many of whom will be glad to find it unencumbered as a rule with scientific names The great feature of Mr Ingersoll's book is, however, formed by the illustrations many of which more especially the coloured plates and the reproductions from photographs are beyond praise Among the best may be reckoned several of the twelve coloured plates drawn by the author's daughter Those of the fallow-deer and the jaguar are reproductions from German works, and in the case of these as well as in that of the water chevrotain on p 342 which is copied from an encyclopædia article by Sir W H Flower, we fail to notice any acknowledgment of the source Special attention may be directed to the photo of the Himalayan tahr on p 262 as showing the shaggy character of the coat which is so completely lost in all museum specimens we have seen On the other hand it may be noticed that on p 240 the author gives a figure of the head of an African buffalo to do duty for that of the Indian wild ox or gaur, while the cut of an urial's head on p 251 is a ludicrous caricature

In general the text is well up to date, including, for instance an account of the pedigree of the elephant, but it is rather behindhand in the matter of giraffes, and likewise in classing all antelopes as members of a single subfamily Moreover, in definitely asserting that the latter animals are recent immigrants into Africa the author ignores the recent suggestion of Mr Madison Grant as to the Bovidæ being an endemic Ethiopian group As instances of error we may refer to an evident mistake in regard to the colour of Pembroke cattle (p 240), and to the reference of the name "ravine-deer" to the blackbuck (p 277) These are, however but trifling slips, and scarcely detract from the general excellence of a most attractive volume

A Christmas bird book from the pen and camera of Mr Kearton is a standing dish to which all young bird-lovers look forward with delight and we can

Fig 1 —Chiffchaff and Nest From Nature's Carol Singers

assure them that they will not be disappointed at the fare their favourite author and artist has provided for the present season This time Mr Kearton has taken up his subject from a more definitely systematic point of view than usual dealing "in a concise and popular manner with the appearance, haunts habits nests, eggs, songs, and call notes of the winged melodists that breed in various parts of the British Islands I have endeavoured" he continues "to describe them in such a way that the reader may be able to identify them for himself or herself in wood and field, and where two species bear a similarity of appearance or song to emphasise the points wherein they differ"

In this aim the author appears to have been successful condensing the necessary technical descriptions

[1] (1) The Life of Animals—the Mammal By E Ingersoll Pp xi+555 illustrated (New York The Macmillan Co London Macmillan and Co Ltd) Price 1s 6d net

(2) Nature's Carol Singers By R Kearton Pp 251 illustrated London Cassell and Co Ltd) Price 6s

(3) An Idler in the Wilds By T Edwardes Pp viii+109 illustrated (London John Murray) Price 6s net

(4) I Go A Walking through the Woods and o'er the Moor Compiled from the works of the late Rev C A Johns and others Pp 79 illustrated (Edinburgh and London T N Foulis) Price 2s 6d net

(5) "Brier Patch Philosophy" By Peter Rabbit Interpreted by W J Long Pp xvii+96 illustrated (London Ginn and Co) Price 6s net

(6) "Birds Shown to the Children" By M K C Scott described by J A Henderson Pp 112 illustrated (London and Edinburgh T C and E F Jack) Price 2s 6d net

of colouring into as small a space as possible, and afterwards elaborating the more interesting details of habits and distribution As in all Mr Kearton's books, the great attraction is however the illustrations, which are from photographs by himself and his brother, and in this volume, were we not afraid of libelling their earlier efforts, we should be tempted to say that the artists have surpassed themselves Be this as it may the charming illustrations in this volume would be hard to beat as our readers may judge for themselves from the sample here reproduced (Fig 1) which was selected almost at random, as where all are excellent it is difficult to make a choice A more attractive gift book for young people fond of birds—as all of them should be and probably are when they have the proper opportunities would be difficult to find

The third volume in the list is, as implied by its title less of a purely natural history than either of the two preceding ones dealing largely with country scenery and country life, the frontispiece depicts a beautiful scene from an old-fashioned English hamlet with thatched cottages, while other illustrations show no less exquisite glimpses of shore and river landscape Certain chapters, such as the one on the flight of the swift and another on the song of the skylark, are however vivid sketches of phases in the habits and life history of birds possessing a peculiar interest and charm of their own, and it is only lack of space that prevents our dwelling on these at some length Both those mentioned are illustrated with photographs of the species to which they are respectively devoted, and many readers will be specially interested in the author's observations with regard to the nocturnal flight of the swift In saying that Mr Tickner Edwardes's little volume although written on different lines, vies in interest with Sir Herbert Maxwell's "Memories of the Months" we are bestowing a very high meed of praise

"I Go A-Walking," which is dated 1907 although it was previously issued in parts and the first of these noted in our columns on its first appearance is a series of brief illustrated biographies of certain selected birds and animals These are no doubt excellent in their way but the charm of the book lies in the illustrations, and since these are reproductions from photographs by Mr C Reid of Wishaw it would be waste of words to add anything in the way of commendation A special feature of the work is the number of illustrations of groups of young birds, and that our readers may judge for themselves as to the excellence of these (and the illustrations generally) we reproduce, by the courtesy of the publisher, one showing a trio of young rooks

FIG 2 —Young Rooks From "I Go A Walking

The fifth book on our list is on a higher plane and of a type totally different from any of the others, dealing mainly with animal psychology, and revealing the thoughtful and speculative mind of the talented author To do justice to Mr Long's ideas and theories in the space of a few lines is a manifest impossibility, and we must be content to refer to his belief that the lower animals "possess a rudimentary mind" and may therefore be accorded "some small chance for immortality" With these sentiments we have no cavil, but when we read the statement that "death to the animal is but a sleep, and the only thought in his head when he lies down for the last time is nature's whisper that he will waken as usual when the right time comes" we would ask the author how many wild animals die so to speak, in their beds? With this brief notice we must leave (and commend) a thoughtful work to the best attention of earnest and thoughtful readers

Last and likewise least is the little volume on birds in Miss Chisholm's "Shown to the Children" series In works of this nature the necessity for abundant illustration overrides all other considerations and if in this instance quantity somewhat exceeds quality it must be borne in mind that forty eight full-page coloured plates form a very liberal allowance in a half-crown book and that the style of execution will probably pass muster among the readers of the book If we except a few sentences such as the statement that blackbirds eat snails the letterpress appears in the main to be just what should be provided for very juvenile readers R L

THE TREATMENT OF CANCER

IT is an appropriate coincidence that the sensational statements made in the daily Press last week respecting the cure of cancer should have as their antidote the scientific discourse "On the Treatment of Cancer by Modern Methods" which was delivered at the Royal College of Surgeons, as the Bradshaw lecture by Mr Edmund Owen on December 12 In an article in the *Pall Mall Gazette* Dr Saleeby went so far as to assert that the conquest of cancer is within measurable distance the means of cure being trypsin a digestive ferment formed by the pancreas and passed in its secretion into the duodenum the upper part of the small intestine

The use of trypsin as a cure for cancer seems to have suggested itself independently to two observers Mr J Beard and Dr Shaw-Mackenzie the former apparently on embryological grounds and the latter because of the comparative immunity of the small intestine from cancer Thus in 105,574 cases of cancer of the digestive tract the small intestine was affected in only twenty [1] Beard found that in mice the subjects of experimental cancer (the Jensen

[1] Shaw Mackenzie [illegible]

tumour), injections of trypsin caused shrinkage and degeneration of the tumours[1] a not unlikely event considering the active digestive properties of trypsin, and his method is stated to have been carried out with success in the human subject by Prof Morton in America

The full report of the work of Prof Morton will be awaited with interest, but, in the meantime, the premature publication of details cannot be too strongly condemned It is well known that trypsin has been tried in this country by many without any startling success, it is possible that it may be valuable in certain localised growths, just as radium and the X-rays are in selected cases, but, on the data available to assert that the conquest of cancer is near at hand is unreasonable and does infinite mischief to science as well as increasing the suffering of the unfortunate victims of this dire malady by hopes that are destined not to be realised

With reference to Mr Beard's experiments on mouse cancer it is to be noted that this so-called experimental cancer is an implantation of the disease into an animal, and not a cancerous metamorphosis of the animal's own tissues a thing very different from spontaneous cancer Chian turpentine violet leaves, Doyen's serum, and a host of other remedies have all at some time or other been vaunted as specifics for cancer, but none has stood the test of rigorous trial

In conclusion an extract from the Bradshaw lecture may be quoted —

"Surgery must not go in advance of facts, or she will assuredly be overtaken and tripped up as she has learnt from sad experience At present it is beyond her power to promise to *cure* cancer, whether by a cutting operation, by X-rays, by Finsen's light, or by any drug or nostrum injected into the blood, taken internally or applied locally Treatment is unfortunately not the same thing as cure, and the most effectual treatment for cancer—no matter how small it may be—is still removal by the knife "[2]

NUBIAN ANTIQUITIES

AN important philological discovery is announced from Berlin Profs Karl Schmidt and H Schäfer who are well known for their work in connection with Coptic literature and Nubian antiquities respectively, have succeeded in making out something of the meaning of some religious documents of the eighth century A D, written in Coptic characters, but in the Nubian language The three Nubian dialects of to-day Kenûs, Mahass, and Danâkil, are not written We have, of course, considerable knowledge of the grammar, &c, of these modern dialects, but of the earlier history of the language but little is known Hence the interest of Prof Schmidt's discovery If the two savants concerned succeed in making out more of the language, we may be able to decipher some of the *few* Nubian inscriptions written in Coptic characters which still exist

In the description of the rock-cut grottoes of Gebel Adda, near Abu Simbel, in Murray's "Handbook for Egypt" (1896, p 977), we find the following passage—"On the walls are some Coptic inscriptions, and on the S wall of the adytum is a long text of 14 lines, in what Lepsius calls 'Christian Ethiopic,' of which another example exists on a rock (now partly broken) at the foot of the cliff on which Qasr Ibrim stands The letters are those of the Coptic alphabet, but the language is unknown" This is the kind of inscription referred to Such records are very rare, and we fear that even when read they will prove to be of religious character, and will not throw the "light on the history of the earliest Nubian races" which the sanguine Berlin correspondent of the *Globe* (December 11) anticipates The discovery referred to is published in the *Abhandlungen* of the Royal Prussian Academy of Sciences under the title "First Fragments of Christian Literature in the Old-Nubian Language"

The Old-Nubian inscriptions of Qasr Ibrim and Gebel Adda are not referred to in Prof Breasted's recently published report on the "Temples of Lower Nubia" (Chicago, 1906) We hope they have not suffered of late years With regard to the grottoes of Gebel Adda, we note that on p 18 of his report Prof Breasted claims to have discovered a fact that has in reality been known for at least ten years, namely, that the ancient Egyptian Viceroy of Nubia, Paser, who cut a "memorial niche" for himself in this rock lived in the reign of Eye (Ai) as well as in that of Harmhab (Horemheb) Prof Breasted errs in his statement that Paser was "heretofore [? hitherto *heretofore* can only refer to matter comprised in Prof Breasted's previous pages] supposed to have been in office only under Harmhab" He will find the fact noted in the 1896 edition of Murray's "Egypt" probably by that indefatigable collector of Egyptian epigraphic material Prof Sayce

Murray's book is especially useful for rock-tombs and inscriptions and has far more detail of sites not usually visited by tourists than Baedeker has, but Prof Breasted has religiously followed his German guide and so has fallen into Baedeker's error of calling the temple of Serret el-Gharb, south of Gebel Adda "the temple of Aksheh" (p 17) This mistake was pointed out by Prof Sayce in the "Recueil de Travaux" for 1895 but still remains uncorrected Aksheh Aksha or Akasheh is many miles away south of Wadi Halfa, there is a village called *Eshka* however, not far off which may be the origin of Baedeker's mistake

NOTES

THE following presidents of sections have accepted office for the meeting of the British Association to be held at Leicester next year —A (Mathematics and Physics), Prof A E H Love, F R S, B (Chemistry), Prof A Smithells, F R S, C (Geology), Prof J W Gregory F R S, D (Zoology), Dr W F Hoyle, E (Geography), Mr George G Chisholm, F (Economics), Prof W J Ashley, G (Engineering), Prof Silvanus P Thompson, F R S, H (Anthropology) Mr D G Hogarth, I (Physiology), Dr A D Waller, F R S, K (Botany), Prof J B Farmer, F R S, and L (Educational Science), Sir Philip Magnus M P

THE Royal Irish Academy held a very successful conversazione in the Academy House on December 4 Their Excellencies the Lord Lieutenant (visitor of the academy) and the Countess of Aberdeen were present and a large and distinguished company accepted the invitation of the president and council Some of the rare manuscripts in the possession of the academy were on exhibition, and attracted much attention, and interesting demonstrations were given in connection with recent scientific developments There were shown by the fisheries branch of the Department of Agriculture and Technical Instruction for Ireland a number of important additions to the marine fauna of Ireland Some new scientific instruments were

exhibited and explained, and there was a notable series of large photographs of Vesuvius taken during the recent eruption

IN the speech of the Secretary for Scotland on December 14, during the debate in committee of the House of Commons on the National Galleries of Scotland Bill the following passage describes his final proposals regarding the accommodation and grant to the Royal Society of Edinburgh —" He had now to mention the arrangements proposed for the housing of the Royal Society For that purpose it was proposed to expend 28 000*l* of the capital in the hands of the Board of Manufactures A sum of 25 000*l* would go to the purchase of a building, and 3000*l* would cover the expenses of fitting up re-decorating the new premises, and transferring the library and other effects of the Royal Society from the Royal Institution The Treasury were giving the Royal Society a grant of not more than 600*l* a year At present the Royal Society received a grant of 300*l* a year which grant was paid by them as rent for the part of the Royal Institution which they now occupied In future the Royal Society would be placed in occupation of their new premises and they would also have the grant of 600*l* a year for scientific purposes and would be free from any obligation to pay rent He thought it would be conceded that the Treasury had been, not extravagant in this matter, but generous "

BY permission of the Lord Mayor the annual meeting of the British Science Guild will be held at the Mansion House on January 28 at 4 p m Mr Haldane the president of the Guild and others to be announced later will speak The Lord Mayor will preside

To celebrate the fiftieth anniversary of its foundation the Geographical Society of Vienna held a meeting on December 15 under the presidency of the Archduke Rainer, patron of the society

THE gold medal offered by the National Geographic Society, Washington for extraordinary achievements was presented to Commander Peary by the President of the United States at a banquet on December 15

THE Berlin correspondent of the *Times* states that on December 14 the German Wireless Telegraphy Company succeeded in establishing wireless telephonic communication between its offices in Berlin and the wireless telegraph station at Nauen, a distance of about twenty-five miles It is claimed that the apparatus can be adapted to any wireless telegraph installation

IN the House of Commons on Tuesday a discussion took place on the wireless telegraphy convention signed at the recent conference in Berlin, an account of which was given in NATURE of November 15 (p 59) Sir F Sassoon moved —" That in view of the experimental and undeveloped condition of radio telegraphy this House regards with apprehension any engagements hampering the complete freedom of action of the State and asks His Majesty's Government to grant a Select Committee to inquire into the proposals embodied in the Berlin Convention previous to ratification " The resolution was withdrawn after Mr Buxton Postmaster General, had announced, in the course of a detailed reply to the criticisms passed upon the convention that a select committee of inquiry would be appointed by the Government at an early period of next session

ON Friday last, December 14, there was opened in the Alexandra Park, in Manchester, a range of houses erected by the Manchester City Council for the unique collection of cacti made by the late Mr Charles Darrah of Heaton Mersey, and presented to the town of Manchester by his widow and sons The houses which were erected at the cost of 2500*l* are admirably suited for the purpose, and provide a suitable building for this splendid collection which comprises about 1200 species and varieties of *Cactaceae*, and about 400 specimens of other succulent plants

A CORRESPONDENT in Osaka sends us a cutting from the *Japan Chronicle* of October 20 in which it is reported that " a remarkable piece of crystal has been discovered on a hill at Masutomi-mura Kita Koma district Yamanashi Prefecture It is 4½ feet long and 1½ feet thick weighing more than 10 000 lb " The information is not definite enough to be of much value, but it may be pointed out that a quartz crystal of the size mentioned (4½ feet by 1½ feet) would weigh about 1000 lb, not 10 000 lb In the collection at the British Museum (Natural History) there is a crystal from Madagascar which is 3 feet long and more than 1 foot thick A crystal in Milan 3¼ feet in length and 5¼ feet in circumference is estimated to weigh 870 lb

SPEAKING at the eighth annual dinner of the members of the Medical Graduates' College and Polyclinic, held in London on December 12 Prof Clifford Allbutt who presided said it is quite impossible for teachers however eminent they may be to teach undergraduates and post graduates at the same time hence the necessity for a post graduate society of this kind The science of medicine is living and the sciences on which medicine was founded are living and post-graduates must move forward with the rest Prof Allbutt suggested that the institution should not rest until it has succeeded in bringing about in this country the establishment of a Ministry of Health

THE report and balance-sheet for 1906 of the Armstrong College Marine Laboratory Cullercoats, shows that the sum of 2048*l* has been received as donations in aid of the scheme to provide a completely equipped laboratory A marine laboratory is to be erected forthwith at a cost of 3000*l*, and Mr Hudleston the owner has agreed to let the laboratory to Armstrong College at a yearly rental of 3 per cent on his outlay An appeal is made for funds to furnish and equip the laboratory when erected, and these may be sent either to Mr A Meek at Armstrong College Newcastle upon Tyne or to Mr George Wilkinson, 1 Mosley Street Newcastle upon Tyne

ON December 6 Mr Alfred Hands delivered a lecture before the Royal Engineers at Chatham on " The Protection of Buildings from Lightning " He showed the extent of damage by lightning by means of a chart of England and Wales on which the positions and nature of objects damaged during a period of about nine years were indicated by coloured spots This included 2485 buildings of which 148 were churches Mr Hands showed that it is impossible to protect buildings efficiently by means of set rules, each case has to be studied separately, and the system of protection applied which the complications of metal in and about the structure show to be necessary Hitherto too much importance has been attached to the form and composition of the conductor and too little to the fact that its efficiency depends almost entirely on the way in which it is applied, and very little on what it is As regards the relative value of iron and copper for conductors so far as the matter concerns conductivity and the dissipation of energy, Mr Hands holds it to be of such trifling importance that it sinks into insignificance

in comparison with considerations of durability A lightning conductor is expected to last for a long time, and iron is, unfortunately, too perishable for the purpose As regards cost, an iron system, if of sufficient size to be fairly lasting, is more costly than an ordinary copper tape one

A LETTER in the *Times* reports the return of Dr Stein from his second exploration of Chinese Turkestan As before, he has combined careful surveys of the Chinese-Indian frontier with archæological work His former surveys of the farther side of the Kuen-lun have been largely supplemented and he has explored more ancient sites, revisiting also the Rawak Stupa, from which he obtained before such important archæological material More ancient documents have been secured, and we await with interest his report and hope that he will bring out another book describing his travels This though it will not possess the charm of novelty which distinguished his "Sand-buried Ruins of Khotan" (see NATURE vol lxx, p 275), and made it one of the most important archæological publications of a decade will still be most interesting as a sequel to his first work and is sure to contain matter of the greatest importance We greatly desire to hear more of the mighty Muztagh ata "Ice mountain Father" and of the other Muztagh in the Kuen-lun with the extraordinary eroded ranges of Yagan-dawan and the impassable gorges of the Yurung-kash as well as of the ancient cities of Khotan with their sand buried treasures of former civilisation

RARE birds observed at Rositten form the subject of notes by Dr J Thienemann in the June and October issues of Reichenow's *Ornithol Monatsberichte* The most noteworthy is the Indian greenish tree warbler *Phylloscopus (Acanthopneuste) viridans*

THE articles in the November issue of *Naturen* include one by Mr N J Føyn on the *Gjøa* expedition under Amundsen for polar magnetic observation a second, by Mr C F Kolderup on the San Francisco earthquake and a third by Mr J A Grieg on animal groups in the Bergen Museum The latter institution, it appears, has been endeavouring to imitate the *régime* inaugurated by Sir W H Flower in our own Natural History Museum and the article contains reproductions from photographs of groups of birds and mammals amid their natural surroundings which have been recently set up at Bergen

A MEMOIR by Prof I Toula on the dentition of *Rhinoceros (Ceratorhinus) hundsheimensis* forms article 2 of vol xx of the *Abhandlungen der k k geol Reichsanstalt* Vienna This rhinoceros which is regarded as a relative of the living *R sumatrensis* was first described in 1901 on the evidence of remains from Hundsheim Altenburg since which date additional material has been obtained In describing the dentition in detail, the author refers to that of other European Tertiary species several of which he splits up into new species and subspecies The *Rhinoceros etruscus* described by Prof W B Dawkins from the forest-bed of Pakefield he makes for example, the type of a subspecies, *R e pakefieldensis* In giving the designation *R megarhinus brachycephala* to a Continental form Prof Toula seems to be unaware that according to the rule adopted by zoologists, this name is preoccupied by *R mercki brachycephala*, Schroder

WE have to acknowledge the receipt of vol v part iii and vol vi, part i, of the Proceedings of the Rhodesia Scientific Association published at Bulawayo In addition to Mr F White's presidential address delivered on November 7, 1905, the former contains notes, by Mr. H Marshall, on birds of the Zambezi valley, geological notes on Rhodesia, by Mr C E Parsons, and petrographical notes on the oldest rocks of South Africa, by Mr F P Mennell The grasses of Rhodesia, by Mr C F H Monro and the Amantabele and other tribes of Matabeleland, by Mr H J Taylor, Chief Native Commissioner, form the chief subjects of the later issue The "black peril" looms large in Mr Taylor's paper The native, according to the author, has recently made rapid strides towards civilisation, and superstition is fast dying out "His mind is becoming more expansive, and his object is to place himself by his own efforts, if possible, on an equal footing with that of the white man There is a new era in the life of the native, and we are at the present time faced with the greatest political question of the day, all other questions sink into insignificance in comparison"

THE Journal of the Quekett Microscopical Club for November (ix No 59), among others, contains a suggestive paper by Mr J Rheinberg on stereoscopic effect and the improvement of the binocular microscope, and a very useful non technical summary of the Mendelian hypothesis with bibliography and suggestions for experiments with microscopic organisms

DR H G GAYLORD of Buffalo, details some remarkable facts suggestive of contagion among mice and rats arising from tumours believed to be cancerous (*Brit Med Journ*, December 1, p 1555) A cage was discovered in which upwards of sixty cases of spontaneous tumours occurred among rats and mice kept in it in the course of three years The fact that the location of the cage was frequently changed and that the stock was entirely renewed without permanent cessation in the occurrence of tumours, indicate that the cage itself was the source of infection

DURING the last three or four years the view has been gaining ground that the spirillar microorganisms met with in certain diseases and known as "spirochætes" are protozoan and not bacterial, in nature, and Schaudinn stated that they were probably a stage in the development of trypanosomes Novy and Knapp, however, again reassert the bacterial nature of these spirochætes on the following grounds —(1) they do not seem to divide longitudinally as do trypanosomes, (2) they multiply much more rapidly than protozoa usually do, (3) unlike trypanosomes, they are unaltered by dialysis against water, (4) they are less affected by heat, and have less avidity for air than trypanosomes and (5) with spirochætes a well-marked active immunity may be induced on inoculation (*Brit Med Journ* December 1, p 1573)

IN the Bulletin of the Imperial Botanic Gardens at St Petersburg, vol vi, part iv Mr N Busch continues his letters from the Crimea describing the plants collected *en route* Mr W I Taliew, writing on the flora around Ssergatsch, a town in the Government of Nischny-Novgorod, notes the gradual immigration of *steppe* plants, and another ecological paper is contributed by Mr B Fedtschenko on the plant associations of the lake near Borowsk indicating that it is an outlier of the more northern lakes

THE importance of forests in connection with the water supply of a country, inasmuch as they regulate the flow of rivers, prevent erosion, and help to conserve moisture, is now generally admitted This subject is touched upon in

the editorial of the *Indian Forester* (September), and is discussed in a letter from Mr A M Lushington, who draws his arguments from a consideration of the sources of the Cauvery Mr Lushington emphasises the necessity of duly conserving the forests at the river sources, and suggests that the help of Government should be invoked to provide the necessary funds, more particularly where the river runs through different States

MUCH attention is paid in various parts of India by the forest departments to the planting of avenues along the roadsides An article describing the trees suitable for the Salem district in Madras, by Mr F A Lodge, is published in the same number of the *Indian Forester* Figs, the wild mango, the tamarind, and the margosa tree, *Melia azedirachta*, are recommended as a first choice, but a more extensive list is given of trees less generally suitable although adapted to special soils Cultural directions are added with regard to setting out nurseries, transplanting and pruning

THE *Bulletin de la Société d'Encouragement* (vol cviii, No 9) contains the oration delivered by Mr Gruner at the funeral of Mr Huet the eminent civil engineer, president of the society

THE report of the judges on the trials of suction gas producers organised by the Royal Agricultural Society has been drawn up by Captain Sankey, and summaries of it are published in the *Engineer* and in *Engineering* of December 14 It forms a valuable contribution to the literature of the subject, and shows conclusively that the suction plant is well adapted for agricultural purposes Although less manual labour is required than with a steam engine, more intelligence is required on the part of the attendant to ensure the production of gas of good quality In the eleven plants of which complete figures are given, the fuel consumption per brake horse-power at full load varied between 1 04 lb and 1 48 lb The winners of the awards priced their plants at almost the same figure, 11 65*l* and 11 77*l* per brake horse power

RECENT developments in aërial navigation form the subject of an article by Major Baden Powell in *Knowledge* for December Commenting on the prevalent view that Santos Dumont's experiments constitute the first case of actual human flight, the author refers to the previous reported records of the Brothers Wilbur and Orville Wright He also expresses doubt as to how far the recent experiments in Paris have effectively disposed of the stability question From Major Baden-Powell's article we further learn that experiments with mechanically-propelled balloons are still receiving considerable attention In particular the Zeppelin airship has again been making trips and a speed of thirty miles an hour has been recorded though it would appear that the estimate was made by theodolite measurements and further information would therefore have to be placed at the disposal of a reader before any conclusions could be drawn as to the velocity relative to the wind A new Lebaudy balloon called *La Patrie* has been built for the French Government Since the appearance of Major Baden-Powell's article it has been reported in the Press that a new explosive has been prepared by the United States Government for use in aeroplane machines constructed by the Brothers Wright

THE Journal of the Franklin Institute (vol clxii, No 5) contains a striking illustration of the historical collection of more than a thousand incandescent lamps, for which the Elliott Cresson gold medal was awarded to Mr William J Hammer, of New York The collection, made during a period covering more than a quarter of a century, embodies a history that could not have been recorded in words and could not be reproduced if destroyed In the same issue Prof Carl Hering describes the Decker battery, a new form of primary battery for large outputs It is the usual bichromate cell the feature of novelty being the construction of the cell and its parts Prof A E Outerbridge reviews recent progress in metallurgy, dealing specially with high speed tool steels ferro-alloys, steel-hardening metals nickel vanadium steel alloys, blast-furnace slag cement, aluminium copper, the great increase in the production of gold and the declining production of silver

IN the *Century Magazine* for December is an article by the Hon W H Taft Secretary of War, U S A explaining why the lock system was adopted for the Panama Canal This question had been referred to a commission of thirteen of the most experienced ship canal engineers both in the United States and abroad The majority of this commission eight in number, advised a sea-level canal while the minority, consisting principally of the American engineers advised a canal with locks at a summit-level of 85 feet above the sea The final decision of the American Government and Congress has been recorded to the adoption of the lock system The reason for this may be briefly summarised as follows —The canal without locks would require a deep cutting, a great deal of which would be rock, through the summit-level at Cuelebra involving the removal of 250 millions of cubic yards The waterway through this cutting would only be 150 feet wide and 40 feet deep It was estimated that it would take sixteen years to complete the work and that the total cost including interest on the outlay, would amount to about 63 millions of pounds The lock canal, on the other hand is estimated to cost half the above sum, and to occupy only half the time in constructing The waterway will vary from 45 feet to 75 feet in depth and the width from 1000 feet over half the length 500 feet to 800 feet over a third and for about five miles 200 feet. The locks are to be in three flights with a rise of 85 feet; or a total lift of 255 feet Next to the locks, the most important work will be the enormous dam that is to be constructed to hold the water from the Chagres River which will form a lake covering an area of 118 square miles and in places eight miles wide the depth varying from 45 feet to 75 feet The dam will in fact be a small artificial mountain about 1½ miles long half a mile wide at the bottom and 135 feet high, the depth of the impounded water being 85 feet at the dam the top of which is to be 50 feet above water level

THE frequently observed fact that the spontaneous ionisation of the air when measured in leaden vessels appears to be greater than when observed in a chamber of any other metal suggests the presence of some radio-active impurity in ordinary lead An attempt to identify this constituent is described by Messrs Elster and Geitel in No 23 of the *Physikalische Zeitschrift* The fact that a solution of ordinary lead does not give an emanation proves that the radio-active element is neither radium, actinium nor radio thorium The active constituent remains in solution when the lead is precipitated as chloride and in this respect resembles radium E and radium F the fact that it shows an α radiation exclusively would suggest that it is probably radium F (polonium) Before this point can be settled measurements will have to be made of the range of its α radiation

In a communication to the Royal Academy of Belgium (Bulletin No 7, p 452) Prof Walthère Spring shows that the material obtained by decomposing a solution of hydrogen sulphide with sulphur dioxide, and formerly described as δ sulphur by Debus, who considered it to be an allotropic form of the element is in reality a hydrate having the composition S_8,H_2O The hydrate has at the ordinary temperature a vapour pressure much smaller than that characterising most hydrates When, however, it is exposed for a long period in a vacuum it gradually loses water a form of sulphur being produced which differs from the known forms in its regenerating the hydrate when left in contact with water It is interesting to note that the composition of the hydrate corresponds with the molecular weight S_8 which has been found by physical methods to characterise sulphur in solution

Mr W B Clive has published a second edition of "Graphs or the Graphical Representation of Algebraic Functions" by Messrs C H French and G Osborn The book has been expanded, chapters having been added on harder graphs and on the slope of a graph

A second popular edition of Mr Oliver Pike's "In Bird land with Field-glass and Camera" has been published by Mr T Fisher Unwin The first edition of this attractive volume was reviewed in our issue of August 30, 1900 (vol lxii, p 417) and it is unnecessary to add anything to the favourable opinion then expressed

We have received tickets for Mr Otho Stuart's revival of *A Midsummer Night's Dream* at the Adelphi Theatre We are glad to know that the management is presenting this delightful comedy which, unlike many of the modern plays, is not based upon impurity or inanity, but provides all who see it, whether children or adults with innocent enjoyment and real delight An arrangement has been made by which schools and parties of students may receive special terms of admittance, for particulars of which application should be sent to Mr C F Level at the Adelphi Theatre

A second edition of Mr J H Stansbie's "Introduction to Metallurgical Chemistry for Technical Students" has been published by Mr Edward Arnold The book assumes that those who use it are practically interested in the common metals but have only the knowledge of their properties gained by every-day observation in the workshop or foundry The scientific study of the subject consequently starts at the beginning The text is practical in character, and will be useful to the technical students for whom it is intended

OUR ASTRONOMICAL COLUMN

Systematic Stellar Motions —In a paper submitted to the Royal Astronomical Society Mr A S Eddington discusses the proper motions of the stars contained in the Greenwich-Groombridge catalogue from the point of view that they are not haphazard, but may be considered as belonging to two defined systems

It has been generally assumed that these proper motions were proper to the individual stars only, but Prof Kapteyn recently concluded that this assumption was erroneous, and that they might be classified into two "drifts," which are in relative motion, the one to the other Mr Eddington's results confirm this theory quantitatively In each drift the velocities relative to the system of axes of the drift are quite haphazard, but this system of axes has a velocity which is defined as the velocity of that drift

On analysing the figures obtained for the regions discussed, in order to find the directions of the two drifts in each region Mr Eddington found that the stars of drift i have a common velocity, relative to the sun, away from a point near to R A 18h, dec +18°, and that the best point for the apex of drift ii is about the position R A 7h 30m, dec +58° The velocity of the first drift relative to the sun is much larger than that of the second, the ratio being about 17 5, and from an investigation of the *magnitudes* of the proper motions there appears to be no appreciable difference in the mean distances of the stars of the two drifts (the *Observatory*, No 377)

The Spectrocomparator —An extremely interesting instrument, devised for the measurement of the spectral displacements in the determination of stellar radial velocities, is described by Dr J Hartmann in No 4, vol xxiv, of the *Astrophysical Journal*

The usual method employed in measuring the "Doppler" displacement has been to measure the displacement of each individual stellar line in regard to the corresponding line in a terrestrial spectrum, but in Dr Hartmann's instrument a large number of lines are compared with those of a standard solar spectrum at one time, so that a stellar spectrum rich in lines, which would, by the older method have taken days to measure, may now be measured in an hour or two Details, too numerous to mention here, are given in Dr Hartmann's paper, and are well illustrated by diagrams and worked examples

Measurements of the Effective Wave lengths in Stellar Spectra —The position of the "effective" wave-lengths in stellar spectra, that is, the position of the radiations which, in the combined radiations of a complete spectrum, appeal most strongly to the eye, is of great importance in double-star observations For this reason Dr H E Lau has determined this position in seventy stars, by Prof Comstock's interference method, and publishes the results in No 4134 of the *Astronomische Nachrichten*

The stars which have been examined are arranged in groups according to the Harvard classification, and the distance between the conjugate spectra of the first order is given for each object This quantity may be converted into wave-lengths by the application of a known factor

Early Observations of Jupiter's Sixth Satellite —On examining the Harvard photographs of Jupiter, Miss Leavitt found the image of the sixth satellite on two taken in 1894 and on nine taken in 1899 These plates were measured, and the results of the measures and their reduction are given and discussed in No ii, vol lx, of the Annals of Harvard College Observatory It appears that Miss Leavitt marked and measured this satellite when examining some of these plates on December 10, 1904, but concluded that it was probably an asteroid near to its stationary point

Observations of the August Meteors —In No 4132 of the *Astronomische Nachrichten* Prof von Konkoly records the results of some meteor observations made at the O Gyalla Observatory in July and August last These results show that the maximum of the shower occurred on August 12, on the night of which 158 meteors were observed at O'Gyalla and 251 at the subsidiary station at Nagy Tagyos On August 13 the corresponding numbers were 111 and 175

GEOLOGY IN THE UNITED STATES AND CANADA

Glacialists will be interested in the short sketch of the drumlins of south-eastern Wisconsin contained in Bulletin No 273 of the U S Geological Survey[1] It is a preliminary record of a detailed study of the post-Pleistocene deposits of the district which embraces part of the ground moraine of the Green Bay glacier—in which most of the drumlins lie—and part of that of the Lake Michigan glacier, as well as an earlier Iowan or Illinoian glaciation The relations of the drumlins to eskers and to the terminal moraines and rock mounds were investigated The map shows most clearly the arrangement of the drumlins to correspond with the lines of flow of the deploying glacier

Bulletin No 265[2] contains a short account of the struc-

[1] Bulletin No 273 "The Drumlins of South eastern Wisconsin. (Preliminary Paper) By W C Aldin (1905)

[2] Bulletin No 265 'Geology of the Boulder District of Colorado By N M Fenneman (1905)

ture and stratigraphy of the district, and such features as mesas, slip faults, and lake basins are incidentally described. The well-known Wyoming beds are still tentatively retained in the Triassic system on very poor evidence, and notwithstanding the different interpretation placed upon them by Mr Darton The main purpose of the paper is to explain the position of the oil-bearing beds at Boulder These are shown to be irregular sandstones in the Pierre shales (Cretaceous) The paying beds are limited to a narrow line over the crest of a shallow anticline and over one or two subsidiary folds Much time and money appear to have been wasted through carelessness in keeping the journals of bore-holes, and by the reckless "shooting" of the wells

Not long ago we had occasion to notice a bulletin by Mr T N Dale dealing with the much-discussed Taconic area The same author has now (Bulletin No 272[1]) called upon his long experience of the region to produce in a pamphlet, of no more than fifty pages, a charmingly lucid exposition of its physical geography With the maps, sketches, and photographs, this will be an ideal guide-book to the district for intelligent students

In Professional Paper No 43[2] Mr Lindgren gives a detailed description of one of the largest copper-producing districts in the United States The oldest rocks are pre-Cambrian granites and schists over them lie Palæozoic formations, comprising Cambrian quartzites, Ordovician limestones, shales possibly of Devonian age, and pure limestones of the Carboniferous Resting unconformably upon the Palæozoic strata are Cretaceous shales and sandstones After the deposition of the latter formation, a second granitic intrusion, with dioritic porphyries, penetrated the rocks in sheets, laccolites, and dykes Then there followed a period of uplift and faulting, succeeded by great volcanic effusions of basalt, rhyolite, and some andesite A remarkable Quaternary deposit, the Gila conglomerate, at the foot of the mountains bears witness to the erosion that has exposed the older rocks in the centre of the district

The ore deposits are primarily dependent upon the intrusions of porphyry, where it came in contact with the limestones and shales of the Palæozoic series extensive contact metamorphism resulted, not only near the main mass, but within the range of influence of the numerous dykes The limestone has suffered most, in some cases being converted into an almost solid mass of garnet Magnetite, pyrite, chalcopyrite, and zinc blende appear to have been intruded into the altered rock from the porphyry magma Subsequently, oxidising waters have converted the sulphides into carbonates, malachite and azurite are the most common ores The zinc blende has been carried away as zinc sulphate The magnetite and garnet have been much decomposed, yielding silica and limonite

These ore bodies, though somewhat irregular, are mostly worked along the bedding, frequently by tunnels, since they lie at no great depth In addition to the above ore bodies, there are numerous veins of pyrite, chalcopyrite, and zinc blende, these have been greatly enriched by the secondary deposition of chalcocite on the pyrites, both in the veins themselves and in the adjoining impregnated porphyry Some interesting observations are made on the action of sulphuric acid solutions, and on the influence exerted by kaolin in enriching the ore A new mineral species, coronadite, a lead-bearing manganite, is described on pp 103–5

This paper contains a good deal of interesting matter and is illustrated by good maps and a series of capital photomicrographs of the ores within the rocks

The thoroughness with which the U S Geological Survey

[1] Bulletin No 272 "Taconic Physiography" By T N Dale (1905
[2] Professional Paper No 43 "The Copper Deposits of the Clifton Morenci District, Arizona By W Lindgren (1905)

tackles problems of local water supply could not be better exemplified than by Professional Paper No 44[1] Naturally the greater part of this bulky volume is occupied by material of purely local interest, that is, with detailed descriptions of well sections, but the brief outline of the geology of Long Island and an account of the elaborate procedure adopted for determining the rate of flow in underground water are capable of more general application

British geologists will be interested to note the suggestion to use the terms "wold" and "vale" in a restricted sense to replace the rather loose use of escarpment and cuesta, which are here more precisely defined, but of more importance, and quite opportune, are Mr Veatch's conclusions as to the cause of the folding of strata at Gay Head, this he unhesitatingly ascribes to the thrust or drag of a continental ice-sheet The volume is liberally supplied with maps

The fifth volume of the General Reports of the Maryland Geological Survey[2] is, as usual, a businesslike and well-finished production It contains the second report on the magnetic work in Maryland, by L A Bauer the third report on the highways of Maryland by A N Johnson, and an elaborate report on the coal deposits of the State, by Prof W B Clark and others

Bulletin No 268[3] contains a descriptive account of

FIG 1 —Bald of Big Yellow Mountain, Mitchell County, N C From "Southern Appalachian Forests

Foraminifera collected by Prof J C Branner from the Monterey shale on Rancho del Encinal, near Asuncion Station, in San Luis Obispo County, California The reader is left in some confusion after studying the brief prelude to the detailed descriptions of Foraminifera, for Prof Branner who writes the geological introduction makes it clear that the shaly series is very frequently sandy, and definite interbedded sandstones are not uncommon On the other hand, Mr Blagg (p 11) makes the statement that "The absence of the arenaceous genera undoubtedly shows the purity of the waters in oceanic circulation during the Miocene, and this evidence is still further substantiated by the fine argillaceous and silt character of the deposit in which the Foraminifera are deposited (*sic*) The Foraminifera, in fact, constitute a large portion of the entire mass of the marl itself" On the previous page (p 10), however, Prof Branner says, "the bulk of this shale is made of diatom skeletons" Plate 1 representing a sandstone intrusion in the Monterey shale, is by no means a convincing illustration

The fossils described in Bulletin No 266[4] were all collected from the Malone Mountain and the immediate

[1] Professional Paper No 44 "Underground Water Resources of Long Island, New York By A C Veatch C S Slichter I Bowman W O Crosby, and R E Horton (1906)
[2] Vol v Maryland Geological Survey (1905)
[3] Bulletin No 268 "Miocene Foraminifera from the Monterey Shale of California By R M Bagg, jun (1905)
[4] Bulletin No 266 "Paleontology of the Malone Jurassic Formation of Texas By F W Cragin, with notes by T W Stanton (1905)

neighbourhood Notwithstanding the presence of the genus Ptychomya, the affinities of its fauna clearly refer the Malone formation to the Jurassic system New species of Perisphinctes, Olcostephanus, Nautilus, Trigonia, Natica, Nerinea, Nerinella, Martesia, Pholadomya, and others are figured and described

Bulletin No 270[1] contains records of borings and shallow excavations, with notes on the nature of the rock From these data sectional elevations have been prepared traversing the district in many directions Information of this kind, in the same handy form, would be of great value to engineers and contractors in the London area as it is no doubt in New York

Bulletin No 267[2] contains a short discussion of the problem of the classification and nomenclature of the great series of alternating magnesian limestones and sandstones known as the "magnesian series" or "Ozark series" (Cambrian and Ordovician) The ore deposits do not appear to possess any striking features

A short description of the stratigraphy of the region (mainly Carboniferous), with particulars of the mineral resources is given in Bulletin No 256[3] There is a coloured map

Taken together Bulletins Nos 247, 251, 263[4] give an

FIG 2—Land Erosion near Marion, N C Showing rapid erosion of soil by heavy rains when the forest cover is reduced or destroyed From Southern Appalachian Forests

excellent survey of the conditions of gold mining in Alaska Nos 247 and 251 deal with the geology of their respective districts, No 263 contains a wealth of information upon all the subjects that fall within the scope of the title, and no miner should venture to Alaska without a copy All three bulletins are well illustrated

A more generalised account of the same region is contained in "The Geography and Geology of Alaska," by A H Brooks (Professional Paper No 45, 1906[5]) This well-illustrated volume deals with the climate, the drainage, the history of explorations and surveys, and the geology. In the last-named section an elaborate table is provided giving the correlation of the strata in the western United States and Canada A bibliography is appended

Professional Paper No 41[1] contains a good deal of useful information upon the mineral resources of the central copper region There is also a short account of the volcanic rocks of Mount Wrangell and of the glaciation of the Copper River basin There are numerous interesting illustrations

"The purpose of Mr Alden's paper[2] is to throw, if possible some fresh light on the relations which existed during the later stages of the Glacial epoch between the glaciers of south eastern Wisconsin" It is an interesting study of the phases of glaciation and deglaciation in an area of moderate size The principal facts are graphically illustrated in a series of admirable maps, prepared by the author to show the relations of the several glacial deposits at different stages

Professional Paper No 30 Parts of this volume[3] are excellent, but we are constrained to ask, For whom is it intended? Is it for the West Kentucky miner? Then why burden him with a dissertation on Carboniferous stratigraphy and palæontology? On the other hand, if it was meant for the help of palæontologists, why should their troubles be increased by recording new species under the title "Lead, Zinc, and Fluorspar Deposits"? As for the new species themselves, they may be found beautifully figured but the diagnoses are very meagre

The bulk of Professional Paper No 37[4] is a dreary mass of statistics relating to the forest conditions of southern Appalachia but it contains a number of illustrations which will appeal to all who are interested in problems of afforestation and water supply The forest suffers from ill-regulated lumbering and from fires, but far more damage is done not to the forest alone, but to the water supply, the scenery and the agriculture of large districts by the clearing of land for farm purposes on high ground and steep slopes The rainfall on the north-western slopes ranges from 40 inches to 50 inches, on the south-eastern slopes from 60 inches to 70 inches, and heavy downpours are common The two figures here reproduced bring out very clearly the cause of the trouble and one of its effects

In Professional Paper No 38[5] is a careful description of the Bingham mining district, where low-grade copper and rich silver-lead ores occur in Carboniferous strata and in the later monzonite intrusions

Professional Papers Nos 40 and 47[6] are two important palæontological works, both are illustrated with a large number of beautiful plates

It is not every mineral district that boasts of so elaborate a memoir as Professional Paper No 42[7] within five years of its discovery This paper deals with the geology, petrology faults, and veins, and gives details of each of the mines The temperature in the Tonopah mines shows an abnormally rapid increase with depth, comparable to that in the Comstock

In Professional Paper No 49[8] a general account is given of the Cumberland Gap coalfield Kentucky All the rocks of this basin are of the age of the Pottsville group of the Pennsylvanian coalfield The field has only been exploited since 1892, eight seams are mined at present, their thickness ranges from 4 feet to 6 feet

for 1901[1] (published 1905) contains, in addition to the summary report (published in 1902), a report on the Klondike goldfields, by R G McConnell, 1905, a report on an exploration of Ekwan River, Sutton Mill Lakes, by D B Dowling, 1904, Dr Barlow's elaborate report on the nickel and copper deposits of the Sudbury mining district, 1904, and other papers Both volumes are illustrated and accompanied by separate portfolios of maps The volume for 1902-3 contains the summary reports for 1902 (published in 1903) and for 1903 (published in 1904) There is also a report on the coalfield of the Souris River, East Assiniboia, by D B Dowling and the "Section of Mines" annual report for 1902

SCIENTIFIC FISHERY INVESTIGATIONS

IN the unavoidable absence of the Chancellor of the Exchequer, Mr R M'Kenna received a deputation at the Treasury on December 18 in support of the application of the Marine Biological Association for a grant to continue the scientific fishery investigations which are at present being conducted in the North Sea and English Channel The deputation was introduced by the Right Hon Austen Chamberlain, M P, ex-Chancellor of the Exchequer, and among those present were Prof E Ray Lankester (president of the Marine Biological Association), Sir Michael Foster, Sir William Ramsay, Mr A E Shipley (chairman of the council), Sir Charles Eliot, Mr Chas Hellyer Mr J A Travers Dr Chalmers Mitchell, Prof L A Minchin, and Dr H R Mill

In introducing the deputation, Mr Austen Chamberlain stated that, as a former Chancellor of the Exchequer, it had been his duty to review the work which had been done by the Marine Biological Association, and he had come to the conclusion that it was most necessary and that it had been efficiently performed He considered that British Governments of both parties should do more to support both science and art Prof Lankester gave a brief account of the history of the Marine Biological Association, and explained the circumstances in which the association undertook, at the request of His Majesty's Government to carry out the English portion of the international scheme of fishery investigations He directed attention to the fact that the present application of the association for funds to continue their researches had received the special support of the Royal Society, which recorded in a strong minute its appreciation of the value and efficiency of the work being done

Mr A E Shipley said the Government has gained directly and in money by entrusting the North Sea work to the Marine Biological Association He referred to the importance of extending over a sufficient period of years the kind of investigation which the association is making Only so can the effects of secondary causes and exceptional fluctuations be eliminated from the essential, primary normal factors While time advances in an arithmetical progression so does the value of the results increase in a geometrical ratio Mr Shipley gave a short *résumé* of the work accomplished and because it has furnished the problems of most pressing importance he confined his remarks chiefly to the plaice During the last four years the association has devoted much hard work to tracing the life-history and the distribution of this species throughout the North Sea, with the result that many important facts concerning it have been established Similar investigations have been carried on, but not yet so thoroughly, into the life-histories the distribution the migrations, and rate of growth of many of the other food fishes the cod, the haddock, the sole the turbot, and others Special experiments have been made on the *Huxley* to determine the vitality and the extent of injury inflicted upon trawl-caught fish by the operations of trawling The hydrographic observations and the investigations into the minute organisms which crowd the surface of the waters and form the ultimate food of fish have been efficiently carried on in accordance with the programme laid down by the international conferences In this work especially the Plymouth steamer, the *Oithona* has supplemented and helped the *Huxley* The association asked for a continuation of the grant which for the last five years the Government has made towards the expense of carrying on the English part of the North Sea international investigations A grant of 6000*l* a year is needed to continue the international work, and a grant of 2000*l* for the work on the south coast, making a total grant asked for of 8000*l* Next spring, for the first time, the International Congress has been invited to meet in England There will be gathered together in London some thirty or forty of the leading men of science from Russia, Finland, Sweden, Norway, Denmark, Germany, Holland and Belgium It will be a pitiful thing, and also a deep humiliation if we have to greet these gentlemen with the tidings that England, who takes from the North Sea far more than all the other eight countries together, more, in fact than 90 per cent of the total yield, is too impoverished to continue to do her share of this important work

Sir Michael Foster, speaking on behalf of the British Science Guild considered that the money asked for ought to be regarded as of the nature of an investment, and not as expenditure He believed that scientific investigation was the only sound foundation upon which fishery legislation could be framed, and that experimental legislation which was the only possible alternative to experimental research would involve the country in far greater expenditure than the small sum required by the Marine Biological Association

Mr Charles Hellyer chairman of committees of the National Sea Fisheries Protection Association speaking as a practical man connected with the fishing industry, emphasised the importance to the industry of the knowledge being accumulated by the scientific investigations now in progress

Mr J A Travers, in the absence of the Prime Warden referred to the support which the Fishmongers' Company had always given to the work of the Marine Biological Association in the belief that an increase of scientific knowledge was bound to be advantageous to the best interests of the fishing industry

Dr H R Mill spoke of the very valuable results which had been obtained from the hydrographical work carried out in the North Sea and adjacent waters during recent years and expressed the view that the time was not far distant when it would be possible to predict the movements of the migratory fishes from a knowledge of the hydrographical conditions of the sea

Mr M'Kenna in reply to the deputation, stated that after what had been said there could be no question as to the value of the work upon which the Marine Biological Association was engaged But the demands upon the national Exchequer were very heavy and as a matter of experience they found that the satisfaction of one demand led to a number of others being brought forward He promised to lay the views expressed by the deputation before the Chancellor of the Exchequer, who would he had no doubt, give them his most careful consideration

AGRICULTURAL RESEARCH

IN concluding a course of Cantor lectures at the Society of Arts on Monday on the subject of "Artificial Fertilisers," Mr A D Hall, director of the Rothamsted Experiment Station, pointed out that only by continued investigation and experiment can a knowledge be obtained of the conditions necessary to make the maximum profit out of the land crops and stock The teacher can only hand on what is already known and much yet remains unknown about the growth of our commonest crops and the action of standard fertilisers Adequate provision for scientific investigation of agricultural matters is of national importance as the following remarks made by Mr Hall show but though a few counties and other local bodies are carrying out demonstrations Rothamsted with its comparatively small endowment, remains practically our only experiment station where problems in agricultural science are studied with the object of making new knowledge and State aid for research amounts only to a few hundred pounds a year for the whole country

The grants of our Board of Agriculture for agricultural

[1] "The Annual Report of the Geological Survey of Canada for 1901 (1905) With separate folio of maps The Annual Report of the Geological Survey of Canada, vol xv 1902-3 (1906)

research during the past year amounted to 425*l*, while the corresponding grant in the United States of America (salaries and administration expenses being excluded in each case) was more than 150,000*l* It is true that in both countries the local authorities also spend some money on agricultural experiments, but the same disproportion would probably be found between the respective amounts if the figures could be arrived at.

Are we to take it, then, that these figures represent the relative importance of the agriculture of the two countries, or does the larger figure indicate the greater need of the American farmer for experiment and investigation? The exact contrary is the case, in the British Isles we have to farm with dear land, dear labour, and a number of charges due to the proximity of a high civilisation Farming in consequence can only pay when there is a considerable monetary return per acre, and the bigger yield necessary involves intensive cultivation, the purchase of fertilisers, and the employment of skill, which are all needless to our competitors on a virgin soil But each increase in the expenditure and skill necessary for the crop means a greater opening for knowledge and investigation, science can do little to save money for the man who merely stirs the surface of a virgin prairie scattering in the seed meanwhile, and then leaves it to take its chance until harvest Compare with such a farmer the highly technical routine of the hop-grower who spends 50*l* per acre before he harvests his crop his repeated cultivations his manurings his sprayings for various ends, it is with this kind of crops that science can find profitable employment

Looking at the average yields of the various countries of the world, we find that Great Britain is the most intensively farmed country, it obtains the biggest crops per acre, it has to spend the most to obtain them Furthermore the biggest crop the greater are the risks of disease and blight the greater are the difficulties in securing high quality Here, then in Great Britain exists the greatest need for knowledge and investigation, we cannot even always beg knowledge from wiser countries for many of our problems are special, and brought about by the very conditions of high farming which prevail here England was the first country to start an experimental station, yet Rothamsted still remains the only institution solely devoted to agricultural research in the British Isles, if we except the farm of the Royal Agricultural Society at Woburn The income of the Rothamsted station, derived solely from private benefaction, is about 2600*l* a year, in the United States each of the fifty-three States possesses a station receiving 3000*l* a year from the Federal Government besides what the State itself may contribute, in addition to the great central department of agriculture to which reference has already been made

SOME NEW METHODS IN METEOROLOGY[1]

PROF BIGELOW has here collected six studies The first four deal with diurnal periods —(i) of temperature, (ii) of barometric pressure, (iii) of vapour tension, electric potential, and coefficient of dissipation, (iv) of terrestrial magnetism, (v) treats of the variable action of the sun and its effects upon terrestrial weather conditions, whilst (vi) is a general review of the status of cosmical meteorology

The immediate occasion, the author tells us, for these studies was the necessity of deciding upon the best lines of work for the new "Mount Weather" Observatory at Bluemont, Va, which is intended to serve as a centre for research in connection with the U S Weather Bureau This observatory is to have on its staff experts in various departments, and there is to be an advisory committee of which Prof Bigelow is described elsewhere as chairman

Several of Prof Bigelow's views as to the prosecution of the higher meteorology have much to recommend them as, for example the following —"If cosmical meteorology is to be established then all rough and ready methods must be abandoned, and the work of computing and discussing the data must be placed in the hands of physicists and astro-physicists who possess scientific instincts and training" (p 48), or again —"We must waste nothing by using bad methods of work and unskilled men" (p 51)

But Prof Bigelow possesses, apparently, a duality in his nature, and the following are examples of his second self.— "In the midst of this concatenation of forces the terrestrial magnetic field stands out as the best unifier or integrator It is the most sensitive and delicate pulse which we possess, having one throb in the solar mass, and the other in its synchronism with the earth's meteorological elements" (p 48). This seems not unworthy of Colonel Starbottle addressing a jury, but what exactly does it mean? Here, again, is what we are told of the sun — "Recent computations indicate that at the centre there is a nucleus which is nearly as solid as the interior of the earth, with a temperature of about 10,000° C, the average density is 1 43 times that of water, and this is located at half the distance from the centre to the surface" (p 39)

Feeling doubts of our capacity to follow with advantage Prof Bigelow's highest flights, we have devoted more attention to his studies on the diurnal variations The view to be taken of these must depend on whether they are intended as examples of the methods to be followed by the Mount Weather Observatory, or whether they are simply illustrations of the "rough-and-ready" methods the abandonment of which the author elsewhere recommends Study i deduces from continuous temperature records at Blue Hill Observatory, and from observations made during or in connection with kite ascents there, the diurnal variation of temperature at a series of heights for every month of the year The final results are embodied in Figs 14 to 25, the diurnal variation being assumed negligible at the height of 3400 metres the whole year round The original data are not given, and the methods of manipulating them are only indicated generally Of the probable value of the results no estimate seems possible Study ii gives some general, but not very lucid information about the diurnal variation of barometric pressure Of the amplitude of the 24 hour term it says, not incorrectly "it is very different at neighbouring stations" Yet Prof Bigelow obtains Fourier coefficients for a composite diurnal inequality based on data from Boston, New York Washington, Buffalo, and Cleveland Again we are told in the general remarks that the amplitude of the 24-hour term is from one-fourth to one-half that of the 12-hour term But in the composite case treated by Prof Bigelow the 24-hour term is larger than the 12-hour term in the summer months and the arithmetic means from the twelve monthly values of the amplitudes seem closely alike for the two waves

In the calculations, the diurnal variation is assumed to be *completely* accounted for by three waves of periods 24, 12, and 8 hours If $[n]$ denote the departure at hour n from the mean for the day, then the contributions to $[n]$ from the 12- and 8 hour waves are respectively

$$\tfrac{1}{2}\{[n]+[n+12]\} \text{ and } \tfrac{1}{3}\{[n]+[n+8]+[n+16]\},$$

and what remains after subtracting these two contributions from $[n]$ is *assumed* to represent the contribution of the 24-hour wave This method cannot be recommended even for rough preliminary work, unless the 24-hour term is largely dominant and the Fourier series is known to converge very rapidly In the present instance the amplitude of the 8-hour wave is, according to Prof Bigelow's figures, about half that of the 24-hour wave from November to February In these months the observational data would certainly give an appreciable 6-hour term The same method is then applied to the diurnal variation of temperature (with sign reversed) as deduced in Study i for heights of 195, 400, and 1000 metres at Blue Hill The results for the 8-hour wave at 195 metres during the summer months at once arrest attention In July, for instance, no hourly value assigned to this wave is positive This seems to be due, not to misprints—though these are somewhat numerous in the tables—but to error in the figures for the diurnal inequality itself If the *twenty-four* hourly differences from the mean are summed algebraically, there is in most months a substantial remainder, showing that the mean value for the day has not been correctly taken

Limits of space allow only of brief reference to other

[1] Studies on the Diurnal Periods in the Lower Strata of the Atmosphere Reprints from the *Monthly Weather Review* 1905 By Prof Frank Hagar Bigelow (Washington Weather Bureau, 1905)

matters. Tables iii to vi, p 23, and numerous curves deal with diurnal variation of vapour pressure at Parc St Maur, and at Blue Hill at several levels Tables vii and viii and Chart xii deal with electric potential at Greenwich for each month of the year, and with seasonal data at Perpignan and Paris From a study of these the author advances in Chart xiii, sect ii, as the representative curve of the diurnal inequality one possessing *five* maxima! A very similar curve—based on results by Zölss and Gockel—is given for electric dissipation The conclusions embodied in these curves cannot be recommended for general acceptance The same remark applies to the conclusion, on p 21, that "the (earth's) electrostatic field varies inversely to that of the solar energy" The sole basis for this view seems to be Table ix, p 24 and Fig 53, which are regarded as proving a parallel variation from year to year between the number of solar prominences and the reciprocal of a quantity supposed to represent the mean annual potential gradient at Greenwich

The diurnal variation of the magnetic field seems to be ascribed to up and down movements of positive ions in the atmosphere, these are supposed to indulge a preference for cold air during the day As to magnetic storms, the author's theory is even less clearly stated, but he apparently regards it as supported by the rapid rise towards 1 p m in the frequency figures given by Mr Maunder for the hour of commencement of magnetic storms at Greenwich from 1882 to 1903 The author is presumably unaware that Mr Maunder has since attributed this sudden rise to a cause having nothing to do with terrestrial magnetism, and that it is not shown in figures he has given for the epoch 1848 to 1881 (*cf Phil Mag*, September 1905, p 306) In opposition to the theory advanced by Prof Schuster and others that the magnetic diurnal inequality is due to electric currents in the *upper* atmosphere the author contends that the source is more directly thermal and confined to the lowest two miles of the atmosphere A comparatively short series of simultaneous observations at suitably chosen high- and low-level stations should be fairly decisive for or against Prof Bigelow's contention

In the above criticisms the author has been regarded as a scientific man whose aim is to convey scientific ideas to other scientific men If his aim is simply to convey to an unscientific public a general idea of the problems which present themselves in cosmical physics with the view of impressing the imagination rather than of appealing to the intelligence the case is no doubt different But on either hypothesis what useful purpose is likely to be served by the indiscriminate collection of statistics and the enunciation of vague hasty theories? A sparing use of theory may serve as a lubricant but theory when heaped upon theory is simply dust clogging the wheels of science

CHARLES CHREE

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

MR J J WELCH has been appointed to the newly-established chair of naval architecture at the Armstrong College, Newcastle

IT is announced in the *Lancet* that the late Dr Gustave Schorstein bequeathed 500*l* to the regius professor of medicine at the University of Oxford for the pathological department of the medical school, 500*l* to the London Hospital, and a sum, which will probably amount to some 10,000*l*, in trust to the University of Oxford, subject to certain life interests When these are expired the capital is to be at the disposal of the University for use as the University may think fit

THE following courses of lectures for teachers have been arranged, among others, at University College, London, in conjunction with the education committee of the London County Council —"The Teaching of Geography to Children," Prof Lyde, "Some Types of Vegetation and the Conditions under which they Exist," Dr Fritsch, both courses beginning on January 17 and "The Principles of Electrical Science during the Past 150 Years," Prof Trouton, beginning on January 19

THE preliminary programme of the second International Congress on School Hygiene, to be held on August 5-10, 1907, at the University of London, South Kensington, has been issued The work of the congress will be divided into eleven sections, each presided over by an authority on the subject dealt with The organising committee is inviting educational and public health authorities, universities colleges, schools, societies, and others to appoint delegates to the meeting, and is appealing for donations to meet the large expenditure involved in organising the congress, which it is estimated will be not less than 3000*l* The president of the congress is Sir Lauder Brunton, F R S and the hon secretaries are Dr James Kerr and Mr F White Wallis

THE report of the Board of Education for the year 1905-6 is of an encouraging nature There is plenty of evidence provided that our national system of technical education continues steadily to improve The report points out that much attention has been paid throughout the country to the extension and improvement of the facilities provided for continuative education There has been marked activity in the establishment of courses of instruction affording special technical training, and the effective character of the many courses organised under varied conditions shows that local circumstances have received the consideration necessary for success in this kind of educational work Technical institutions affording whole-time training for those who can give two or more years to study after completing a secondary school course have improved and multiplied their courses of technical instruction The multiplication of courses requiring the whole time of students is a gratifying indication of the growing appreciation of the value of the work of the technical school, but this appreciation is not confined to whole-time instruction The improved organisation of the varied institutions engaged in supplementing the training which a youth receives in the office or workshop has borne fruit in many practical developments demonstrating the extent to which such further education may become a recognised element in the lives of our youths The report which runs to 106 pages deals fully with every department of elementary secondary, and technical education and shows conclusively that political controversy notwithstanding valuable work is being accomplished in the schools

SOCIETIES AND ACADEMIES

LONDON

Royal Society November 22 —"The Structure of Nerve Fibres" By J S **Macdonald** Communicated by Prof C S Sherrington, F R S

Nerve fibres teased in harmless saline solutions and examined under the microscope exhibit a series of varied appearances which are distributed in a constant order in the length of the fibre This orderly distribution is explained as due to the electrical current which traverses the fibre inwards from each injured point and which leaves the fibre to traverse the salt solution at certain definite "kathodal" points

At each injured point the source of the current the colloid material is precipitated and is surrounded by an aqueous solution By the use of definite reagents the solution is found to be a concentrated solution of a potassium salt probably potassium chloride The author in a previous paper has directed attention to the importance of this fact when injury is considered as the fatal consequence of a violent "excitation," and to the probability that "excitation" is the outcome of such a desolution of colloid material and liberation of inorganic salt to diffuse and give rise to electrical change At kathodal points a similar set of conditions is observed, in origin secondary to those already described at the current source

The injury region is abruptly limited by an adjacent "anodal region," where the material of the nerve fibre has an exceptionally fluid appearance, except in so far as this fluidity is disturbed by secondary acid formation and diffusion

The anodal region passes into the kathodal region through a graduated series of coagulative change, attended

by an increasing density of granule formations (precipitated proteid)

The distribution of potassium salt in the solutions within the fibre can be mapped out, not only by definite potassium precipitants but also by dyes which are "salted out" by potassium salts This fact is held to be of importance where in other recorded instances the "staining" effects of these dyes have been observed in nerve cells and in cells of secretory glands, since in these cases also the staining effects observed may be due to intracellular solutions of inorganic salts

The author has also made observations upon the form in which the proteid matter is precipitated in regions of the fibre of different coagulation intensity These observations have resulted in the opinion that the "neurofibrils," which are commonly described as structural elements of nerve fibres are precipitates of proteid making an appearance only when the conditions determining coagulation have a certain low value

November 22 —"On Opsonins in Relation to Red Blood-cells" By Dr J O Wakelin **Barratt** Communicated by Dr C J Martin, F R S

It is shown that—

(1) By employing phagocytosis as a test of the presence of red blood-cell opsonin and avoiding spontaneous phagocytosis by suitable conditions of experiment quantitative determinations of the opsonic content of serum may be made

(2) In the experiments made, the interaction of opsonin and red blood-cell proceeded at a rate corresponding to that exhibited in a bimolecular stoichiometric reaction

Royal Microscopical Society, November 21 Mr A N Disney vice-president, in the chair —The use of a top stop for developing latent powers of the microscope J W **Gordon** The author exhibited his apparatus, which had previously been shown to the society, and pointed out that a top stop enables the microscopist to vary the proportion between the refracted and the unrefracted light which passes the instrument and thus to render conspicuous a particular feature of the object In illustration of the results thus reached he exhibited photographs taken with an achromatic oil immersion objective of N A 1 0 to demonstrate how by means of a top stop, the objective in question could be made to equal the performance of an objective of much wider aperture

Physical Society, November 23 —Prof J Perry, F R S, president, in the chair —Electric radiation from bent antennæ Prof J A **Fleming** An account of experiments at University College, London, with radiating antennæ consisting of bent wires having the property of radiating electric waves more strongly in some directions than others The receiving arrangement consisted of a thermoelectric oscillation-detector contained in a double test-tube like a Dewar vacuum-vessel Four copper strips pass down the inner tube and platinum wires soldered to them are sealed through the glass One pair of these are connected by a fine constantan wire and the other pair by a tellurium bismuth thermojunction A high vacuum is made between the test-tubes If electric oscillations are sent through the constantan wire and a galvanometer connected to the thermojunction, this receiver can measure the root-mean-square value of the oscillations induced in any receiving antenna when the fine wire is inserted between the antenna and the earth The receiver used gave deflections almost exactly proportional to the square of the current passing through the fine wire This receiver was inserted between an earth-plate and a vertical receiving antenna The transmitting antenna consisted of a similar wire and plate Readings were taken of the current in the receiving antenna, and plotted out as polar curves corresponding to the various directions of the free end of the transmitter Curves show that the intensity of radiation in various azimuths for constant distance between receiver and transmitter becomes more unequal as the ratio of horizontal to vertical part of the transmitter increases Also all the polar curves show a minimum radiation corresponding to a direction of the free end of the transmitter such that it makes an angle of 70° to 75° with the line joining the earthed points of the transmitter and receiver The form of the polar curve observed for the same sending antenna, but with different distances between sender and receiver, varies as it should do by theory A large number of forms of antenna were examined Similar effects observed by Mr Marconi in the case of bent receiving antennæ are explained, and it is shown that these effects cannot be explained without admitting three sources of electromotive force in the bent receiving antennæ —(1) that due to the magnetic force of the incident wave, (2) that due to the electric force, and (3) an electromotive force due to the periodic insertion and removal of lines of magnetic force from the nearly closed loop formed by the bent antennæ —Auroral and sun-spot frequencies contrasted Dr C **Chree** The author has already investigated the relationships between certain phenomena of terrestrial magnetism and sun-spot frequency The present paper makes similar comparisons between sun-spot frequency and the frequency of auroras The sun spot data utilised are from the big table of Wolf and Wolfer covering the long period 1749 to 1901 Mean values have been calculated from this table for each month of the year One object was to see whether there was appreciable variation in the mean sun-spot frequencies for individual months of the year The differences between the means for individual months proved to be by no means negligible when calculated from thirty-three consecutive years, or from groups of thirty-three or thirty nine years selected as representing sun-spot maximum and minimum A comparison is instituted between mean sun-spot frequencies and mean auroral frequencies calculated for the same group of years During the periods dealt with there seemed reason to believe that variation occurred in the unit of auroral frequency To eliminate such uncertainties as far as possible, a period say poor in sun-spots is contrasted with two equal periods rich in sun spots, one preceding and the other following it An investigation is made as to whether the annual variation of auroral frequency is the same in years of many as in years of few sun-spots The evidence is not perhaps altogether decisive, but, so far as it goes it points to the conclusion that *relatively* considered, the annual variation is more pronounced when sun spots are few than when they are numerous There seems however to be a conspicuous difference between the variation in the annual auroral frequencies derived from the south and the north of Scandinavia At first sight the much greater length of time for which records exist suggests that aurora lends itself more readily than terrestrial magnetism to a comparison with sun spots - The electrical resistances of alloys Dr R S **Willows** Lord Rayleigh has given a theory intended to account for the high resistance of alloys compared with that of the constituent metals The author attempts to put this theory in evidence by measuring the resistance of an alloy with direct and also alternating currents At the instant of reversal of the latter the back E M F will assist the external E M F, and hence more current will pass, *i e* the resistance will apparently be reduced No spurious resistance could be detected A minimum accuracy of 0 02 per cent is attained

Mathematical Society, December 13 —Prof W Burnside, president in the chair —The form of the surface of a searchlight reflector C S **Jackson** The light from a source must be reflected so as to pass horizontally through a narrow vertical slit The equation of the surface is found to be of the form $r+\rho=$const where r is the distance of a point on the surface from the source, treated as a point, and ρ is the perpendicular distance of the same point of the surface from the slit treated as a vertical line The practical construction of the surface is explained The Diophantine equation $x^n - Ny^n = z$ Major P A **MacMahon** A method is explained for obtaining the arithmetically independent solutions of the Diophantine inequality $\lambda x \geq \mu y$ by forming the descending intermediate series of convergents to the continued fraction μ/λ The forms of the arithmetically independent solutions of the Diophantine inequality $x \geq N^{m} y$ are deduced, and the properties of the number z, which can have the form $x^n - Ny^n$, are determined —Asymptotic expansion of integral functions defined by generalised hypergeometric series Dr E W **Barnes** The series in question satisfy

a linear differential equation which is a generalised form of that satisfied by the ordinary hypergeometric series, and the asymptotic expansions are related to the form of the differential equation In the most important cases the asymptotic expansions become exponentially infinite at infinite distances—The potential equation and others with function given on the boundary L F **Richardson** The paper suggests a tentative method for arriving at an approximate solution of the problem of steady flow of heat in a homogeneous solid with given surface temperature by beginning with the problem of variable flow in a solid of variable diffusivity which tends to zero on the boundary—The limits of real variants J **Mercer** The paper is occupied with generalisations of Cauchy's theorem which is expressed by the formula

$$\lim_{n=\infty}(X_{n+1}-X_n)=\lim_{n=\infty}(n^{-1}X_n)$$

Royal Astronomical Society, December 14—Mr W H Maw, president, in the chair—Solar parallax papers No 5 examination of the photographic places of stars published in the Paris Eros Circular A R **Hinks** Comparisons had been made of the photographic places of stars obtained at Paris, Bordeaux, Catania, San Fernando, Toulouse and Algiers, showing many discordances, some of considerable amount The Algiers places were specially affected by "magnitude equation," the cause of which was very obscure It appeared that many of the star places are affected by errors much larger than those considered permissible in the Astrographic Catalogue—Account of the Oxford Astrographic Catalogue, vol i H H **Turner** The volume in question, which has just been published contains measures of rectangular coordinates and diameters of star images on plates with centres in dec $+31°$ The complete catalogue will consist of eight volumes, one of which will be devoted to discussions—Notes on some spectroscopic observations of the sun H F **Newall** The observations were first made with the 25 inch equatorial at Cambridge (the Newall telescope), and later with a fixed horizontal telescope, a cœlostat and auxiliary mirror the latter equipment appeared to possess considerable advantages An account was given of the preliminary experiments, the instrumental arrangements were described and some results were given of the photographic study of the bands and flutings in the spectra of sun-spots—Note on the approaching return of Halley's comet A C D **Crommelin** The author directed attention to a paper by Dr A J Ångström published in 1862, in which a mean period for the comet of 76·93 years was deduced, with inequalities due to the action of Jupiter and Saturn Dr Angstrom's results give 1913·08 for the time of the next perihelion passage while that given by the Count de Pontécoulant is 1910·37 In view of this large discrepancy of 2·7 years, it is most desirable that the perturbations should be independently computed Before the last return in 1835 there were at least five independent determinations of the orbit, and it would be a great misfortune if there is a serious error in the prediction of this return after the great success achieved in 1759 and 1835—Photographs of Mira Ceti in 1897 and 1906, by Father **Sidgreaves**, were shown There were marked differences in the relative intensities of the hydrogen lines—Dr **Lockyer** also showed photographs of the star taken at its present maximum

MANCHESTER

Literary and Philosophical Society, November 13—Mr C Bailey in the chair—Luminosity produced by the rubbing or knocking together of various forms of silica R L **Taylor.** The luminosity is connected in some way with the breaking away of small particles, mostly in the form of dust Mr Joseph Burton finds that whereas ordinary felspar only shows this property in a very small degree, the same substance previously heated almost to fusion shows it nearly as well as quartz Common glass does not show it, but a specimen of glass "frit," rich in lead and very hard, does to a slight extent The luminosity may be partly due to the hardness of the material, but that it is not entirely so is shown by the fact that whereas a slight luminosity is shown when a piece of corundum or a piece of native emery is rubbed against a piece of silica, there is none whatever when two pieces of corundum or two pieces of native emery are knocked together There is a curious odour produced by the impact of any of these bodies which become luminous, an odour which has been compared to that of ozone, but Mr Taylor has not been able to verify that observation Mr F Jones and Mr Burton also made careful tests for ozone, and both failed to obtain any evidence of its presence—The proembryo and bulbils of *Lamprothamnus alopecuroides* (Braun) Miss M **McNicol.** This plant, which occurs in various countries of Europe and also in Africa, is characterised by the possession of unicellular bulbils or tubercles, formed by the transformation of rhizoids

CAMBRIDGE

Philosophical Society November 12—Dr Hobson president, in the chair—(1) Electrification produced by heating salts; (2) secondary Röntgen rays Prof **Thomson**—The specific heat of gases at constant volume and high pressure W A D **Rudge** The author has determined the specific heat of carbonic acid by heating the gas in small steel bulbs immersed in a calorimeter containing paraffin The value obtained was about 0·45 for a temperature range of from 36° to 60°, when the gas was under a pressure of about 480 atmospheres—The radio-activity of the alkali metals N R **Campbell** and A **Wood** It is found that potassium salts show a greater radio-activity than any substance examined which does not contain a "radio active element" The activity is an atomic property, and is not due to any impurity The rays from potassium vary in penetrating power, the most penetrating rays are similar to the β rays from uranium An activity of the same nature is observed in rubidium, but could not be detected in cæsium, sodium or lithium The rays from rubidium are far less penetrating than those from potassium The ionisation caused by the rays from potassium is about 1/1000 of that caused by the β rays from a similar quantity of uranium An apparently successful attempt has been made to obtain a photographic impression caused by the rays from potassium—A relation between the ionic velocity and the volume of organic ions in aqueous solutions G A **Carse** and T H **Laby.** This is a continuation of a previous paper (Proc Camb Phil Soc, xiii, p 287, 1906) It is found that the product ionic velocity × linear dimension of the ion or *va*, is sensibly constant for the ions of twenty two amines, the mean value being 20·2, for seven homologues of aniline 18·8 for thirteen pyridines and quinolines 20·3 for five phosphines 17·6, &c The linear dimension of an ion is taken as proportional to the cube root of the ionic volume, which is deduced from molecular and atomic volumes It is shown from hydrodynamical considerations that va = const × (term depending on ionic shape)

November 26—Dr Fenton vice-president in the chair—A delicate reaction for carbohydrates Dr **Fenton** When bromo or chloro methylfurfural reacts with sodio-malonic ester in alcoholic solution a product is obtained solutions of which exhibit an intense blue fluorescence The reaction is extremely delicate, and serves to detect the most minute trace of the above named derivatives of methylfurfural It is further shown that all hexoses and polysaccharides, glucosides, &c which contain a hexose residue yield bromo-methylfurfural when acted upon by hydrogen bromide under appropriate conditions and they may therefore be readily identified by the formation of this fluorescent product—Xanthoxalanil and its analogues S **Ruhemann** The author has studied the action of ethyl oxalate on acetanilide in the presence of sodium ethoxide and has found that the compound thus formed, which is called xanthoxalanil, has the formula $C_{20}H_{12}O_3N_2$—The influence of a strong magnetic field on the spark spectra of titanium chromium and manganese J E **Purvis.** The strength of the field was 40 000 units and Prof Liveing's 21 feet concave grating spectroscope was used The general results showed that most of the lines were divided into triplets of which the middle constituent was at least twice as strong as the two outside ones although the three constituents of several lines appeared to be more nearly equal A number of lines were divided into four, and the two outside constituents of some were weaker and more diffuse than the two middle ones, whilst in several they appeared to be equally strong

Chromium λ 2866·80 appeared to divide into eight, only seen separately when analysed by a calcite prism, 3147·23, 2855·73, 2757·75 were divided into six, also only seen separated on analysis, and 2861 is divided into five. The titanium line 3252·03 is divided into six. The distances of the constituents of the divided lines were measured for a considerable number of the strongest lines, and the values of $d\lambda/\lambda^2$ calculated from them. It appeared that amongst the lines which had more than three constituents, the values for several were simple multiples of one another, and in several instances the constituents of different lines had the same values, the same general appearance and polarisation. Also the values of $d\lambda/\lambda^2$ for some lines appeared to be simple multiples of those of other lines.—The solubility of stereoisomerides in optically active solvents: H. O. **Jones.** The statement, found in certain text books, that the solubility of two optical antimers *must* be different in an optically active solvent has been put to the test of experiment, and it has been found untrue. In the cases of *d*- and *l*-camphoroximes and of *d*- and *l*-camphors in *l*-amylbromide and in dextrorotatory turpentine as solvents, the solubility of the *d* and *l* compounds was found to be the same.—Estimation of copper: W. H. **Foster.** An attempt to employ the method of Wood and Berry for the estimation of sugar, and that of Jones and Carpenter for the estimation of hydroxylamine to the determination of copper, especially in mixtures. The method was found to be simple and accurate with copper solutions using grape sugar as reducing agent. With mixtures of copper and other metals the results were generally unsatisfactory, being high when sugar was the reducing agent employed and low when hydroxylamine was used. Phenylhydrazine gave better results than hydroxylamine, but these were also below those required by theory. The method, which is really a modification of that of Schwarz, can be recommended for solutions of copper salts alone, or for solutions containing only small quantities of other metals.—The maturation of the germ-cells in the saw-fly *Nematus ribesii* (third note): L. **Doncaster.**

DUBLIN.

Royal Dublin Society, November 20.—Sir Howard Grubb, F.R.S., vice-president, in the chair.—Some injurious fungi found in Ireland: Prof. T. **Johnson.** The author dealt with certain fungal diseases, mainly from the economic aspect, such as yellow-blight and scab in the potato, "Phoma" rot in mangel and turnip, onion rot, and barley leaf-streak. The paper ended with an account of the author's discovery of the American gooseberry mildew on the red currant in co. Kilkenny, and of the steps taken by the Irish Government to check the spread of this mildew in Ireland.—A contribution to the study of evaporation from water surfaces: J. R. **Sutton.** The observations and experiments were made at Kimberley, South Africa, and under meteorological conditions, *i.e.* in the open air. It is provisionally concluded that while differences between the vapour tensions at the water surface and in the open air are competent to influence the rate of evaporation to a large extent, the intensity of the effect of vapour-tension differences is profoundly modified by the relation the temperature of the dew point bears to the temperature of the air, or, in other words, is profoundly modified by the relative humidity. The water temperatures are, as such, probably of no great importance, initially at any rate, but when considered in conjunction with the temperature and relative humidity of the air, an influence becomes apparent which so far as is known has not hitherto received due recognition. It seems to be extremely probable that after the relative humidity of the open air and the difference of vapour tension have been allowed for, much of the observed evaporation from whatsoever form of water surface or type of gauge, is due to convection currents. The effects of insolation are discussed both as regards evaporation at sea and from land surfaces, and the conclusion is drawn that too much importance has hitherto been attributed to this source of energy. In a series of experiments on the effects of electrification no difference was detected between the evaporation from insulated and uninsulated copper evaporating vessels, other than trifling differences which may be due to experimental error.

EDINBURGH.

Royal Society, November 19.—Dr. R. H. Traquair in the chair.—A new Siphonogorgid genus, with descriptions of three new species: J. J. **Simpson.** These organisms were obtained from the shallow waters of the Indian Ocean, and presented features which quite differentiated them from the other known genera of the same family.—Craniometric observations on the skull of *Equus prejvalskii* and other horses: Prof. O. Charnock **Bradley.** The general conclusions were that the wild horse had a long, narrow face, the Iceland or forest type a short, broad face, while the Celtic type occupied an intermediate position; that the orbit of the wild horse was elongated and placed far back as compared with the rounded orbits of the two other types.—Skulls of horses from the Roman fort at Newstead, near Melrose, with observations on the origin of domestic horses: Prof. J. C. **Ewart.** From a careful study of these skulls, thirteen in all, the author obtained fresh evidence in support of his theory that the present domesticated horses are descended from three distinct types, namely, the wild horse of the Gobi Desert, the Celtic type, and the forest type. The evidence from length and shape of skull, and from the estimated heights of the horses of which the skulls had been found near Melrose, was thoroughly examined, and there seemed little doubt that the Romans possessed horses of from twelve to fifteen hands in height belonging to the three types named. A remarkable feature which seemed to have hitherto escaped notice was the manner in which the forward part of the skull was bent with reference to the base, giving to some types a Roman-nose aspect, to others a straight form of face. An interesting point was that the amount of bending varied with the age of the animal, being (for example) bent at birth in the case of the wild horse, then becoming straight at sixteen months, and, finally, bent again in the adult.—The inversion of cane sugar by optically active acids: Theodore **Rettie** and Dr. W. W. **Taylor.**

December 3.—Prof. Crum Brown, vice-president, in the chair.—The sporulation of *Amoeba proteus*: Prof. J. Y. **Simpson.** The paper gave an account of the sporulation in *Amoeba proteus* without encystment, describing certain specific nuclear changes, and raising some questions in connection with the nuclear changes in the allied species *Pelomyxa palustris*.—Results of removal and transplantation of ovaries: Dr. F. H. A. **Marshall** and W. A. **Jolly.**—The influence of an excessive meat diet on the osseous system: Dr. Chalmers **Watson.**—The effects of a meat diet on fertility and lactation: Dr. B. P. **Watson.**—The effects of a meat diet on the minute structure of the uterus: Drs. Malcolm **Campbell** and Chalmers **Watson.** These three papers treated of different aspects of the same general question. In the first it was shown that in the offspring of rats fed on an excessive meat diet the osseous system was defective. The bones were invariably too soft and vascular, and frequently showed structural changes like those of rickets in the human subject. The blood-forming cells in the bone marrow were also affected, being at first increased in number and later diminished. In the second paper it was demonstrated that the reproductive power of rats fed on an excessive meat diet was much below that of rats fed on a bread-and-milk diet. Further, when the meat-fed rats had litters they were less able to feed their young owing to smaller development of mammary tissue. The third paper contained a description of the minute structure of the lining membranes of the uterus in rats fed on different diets. The prolonged use of an unphysiological diet, such as an excessive meat diet, induced structural changes in the mucous membrane of the uterus, and these changes were most pronounced in animals in which the faulty feeding was begun when the animals were weaned. Such animals were invariably sterile.—The minors of a product determinant: Dr. Thomas **Muir.**

PARIS.

Academy of Sciences, December 10.—M. H. Poincaré in the chair.—The division of labour amongst bees: Gaston **Bonnier.** The author's experiments during last summer show that the division of labour is carried out to a surprising extent among bees. Bees which are seeking for

pollen or nectar do not carry it, but merely carry the news to the hive. A number of bees are sent out to strip the flowers, a number carrying pollen only, others nectar only, others again water only, when water is needed. The number sent out is proportional to the number of flowers to be stripped, and by marking the bees with coloured talc it was proved that each bee confined itself for the time being to one class of work. The same bee might be seeking for flowers in the morning and collecting in the afternoon, but did not change the nature of its work without returning to the hive. There seemed to be something in the nature of a working arrangement between the bees of different hives, as when the work of clearing a certain area of flowers had once been commenced by a few bees from one hive, these collectors were not interfered with by bees from other hives.—Some scientific discoveries of Leonardo da Vinci: P. **Duhem**. A study of the effect of the scientific writings of Leonardo da Vinci on the work of Mersenne, Roberval, Descartes, Fabry, and Huygens.—Glycosuria without hyperglycemia: R. **Lépine** and M. **Boulud**.—The theory of ensembles: Félix **Bernstein**.—The power of orthogonal systems of continuous functions: Erhard **Schmidt**.—The calculation of limits: L. **Fejér**.—A class of differential equations reducible to linear equations: M. **Rivereau**.—The phenomena of magnetic rotatory polarisation in crystals: Jean **Becquerel**.—The motor effects of high frequency currents: H. **Guilleminot**.—A colour reaction given by reducing sugars by *m*-dinitrobenzene in alkaline solution: MM. **Chavassieu** and **Morel**. A violet colouring matter is produced. It is neither more nor less characteristic than other colour reactions of aldoses and ketoses, but has the advantage of being very easy to carry out.—A tetrabromo-derivative of methylethylketone: M. **Pastureau**. The ketone is converted into a peroxide by the action of hydrogen peroxide in acid solution, and this submitted to the action of bromine. The tetrabromide thus formed has been shown to have the constitution $CH_2Br—CO—CH_2—CBr_3$, since when heated with potassium carbonate it gives acetol.—The distribution of phosphorus in foods: M. **Balland**.—The distribution of vicianine and of its diastase in the seeds of Leguminosæ: Gabriel **Bertrand** and Mlle. L. **Rivkind**. About forty species were examined, and most of them were found to contain a diastase capable of hydrolysing vivianine. The glucoside was only found in plants of the genus Vicia, and the distribution of the two substances was very irregular even in this one genus. *Vicia narbonensis*, for example, contains neither diastase nor vicianine.—The composition of vegetable juices extracted from roots: G. **André**.—The respiration of seeds in the state of latent life: Paul **Becquerel**. It has been found that light, the teguments of the seed, and the state of hydration are all important factors in the respiration of the seed, and the effect of these may be sufficient to explain the variable results obtained by different workers on this subject.—Pollen, its origin and transformation: Germand **Vert**.—A tumour in an invertebrate, *Sipunculus nudus*: Marcel A. **Hérubel**.—A new order of dinoflagellated parasites, Blastodiniæ: Edouard **Chatton**.—The interpretation of some results in radiotherapy and an attempt at fixing a rational technique: J. **Bergonié** and L. **Tribondeau**.—The conglomerates of Messina and those of the Glokova-Varassova synclinal in Greece: Ph. **Négris**.

CALCUTTA

Asiatic Society of Bengal, November 7.—Latitude of the Presidency College Observatory: Babu Phanindra Lal **Ganguli**. A simplified method of making approximate calculations in recording observations at the Presidency College Observatory.—Further notes on earwigs (Dermaptera) in the Indian Museum, with the description of a new species: M. **Burr**. Records of new localities and the description of a new species of the genus Anisolabis.—Notes on the habits of the earwig, *Labidura lividipes*, Dufour: Dr. N. **Annandale**. This earwig is sometimes very common at light during the hot weather and rains. It uses its forceps in opening and folding its wings.—Cirrhipèdes Operculés de l'Indian Museum, de Calcutta: M. A. **Gruvel**. An account of the sessile barnacles of the Indian Museum collection, with descriptions of a new genus, Pyrgopsis, and of new species, four of the genus Verruca and one of Balanus. The genus Pyrgopsis is allied to Pyrgoma.—Note on the Houbara or bastard bustard (*Houbara macqueenii*): Lieut.-Colonel D. C. **Phillott**. An account of the habits of this bird, its food, way of hiding, &c.—Descriptions of two new Indian frogs: G. A. **Boulenger**. The species are *Rhacophorus taeniatus* from the plains of Bengal, and *Ixalus annandalii* from the Sikkim Himalaya.—Notes on pollination of flowers in India, Nos. 1–3: I. H. **Burkill**. The author describes (1) the pollination of *Thunbergia grandiflora* in Calcutta by the boring bees, *Xylocapa latipes* and *X. aestuans*; (2) the pollination of *Corchorus capsularis* and *C. olitorius*—the two jute plants—in many places in Bengal and Assam; (3) the pollination, as observed in the Simla Hills, of the flowers of *Adhatoda vasica, Dicliptera bupleuroides, Morina persica, Salvia lanata, Scutellaria linearis*, and *Teucrium royleanum*.—*Ascaris lobulata*, Schneider, ein Parasit aus des Darms von *Platanista gangetica*: Dr. v. **Linstow**. A brief note upon the features of this parasitic worm.—Notes on the fresh-water fauna of India, No. ix., descriptions of new fresh-water sponges from Calcutta, with a record of two known species from the Himalayas and a list of the Indian forms: Dr. N. **Annandale**. Two new species and a new variety of Spongilla, a new species of Ephydatia, and two of Trochospongilla are described from a tank in Calcutta. *Spongilla carteri*, Bowerbank, and *Ephydatia robusta*, Potts, are recorded from a lake situated at the height of 4500 feet above sea-level in the Central Himalayas on the evidence of floating gemmules. The list of Indian fresh-water sponges now includes nine species and varieties of Spongilla, four of Ephydatia, and two of Trochospongilla. The species recorded from Bombay are mostly different from those occurring in Calcutta.—Notes on fresh-water fauna of India, No. x.: *Hydra orientalis* during the rains: Dr. N. **Annandale**. Four tentacled individuals of the polyp have been found during the rains bearing four tentacled buds but without sexual organs. At this season they confine themselves to deep and densely shaded parts of the tank, and are small and colourless.

NEW SOUTH WALES

Royal Society, September 5.—Mr. H. A. Lenehan, vice-president, in the chair.—Port Sydney: L. **Hargrave**. The paper showed how Port Jackson might be made an up-to-date port without tampering with vested interests, present traffic, or riparian rights. The accommodation shown was 8000 yards of quay, with 40 feet of water, six miles from Redfern.—The international rules of botanical nomenclature (adopted by the International Botanical Congress of Vienna, 1905): J. H. **Maiden**. The author gives an account of the modern attempts to evolve laws for a settled nomenclature, beginning at the International Botanical Congress of Paris, 1867.

Linnean Society, October 31.—Mr. Henry Deane, vice-president, in the chair.—Contribution to our knowledge of the action of rennin: A. H. **Moseley** and Dr. H. G. **Chapman**. It was noted (1) that when milk which showed an acid reaction to litmus was neutralised with alkali, rennin ceased to produce its customary clot, and (2) that the addition of quantities of alkali insufficient to produce neutrality of reaction to litmus inhibited the clotting of the milk with rennin. Upon investigation it was found that this action was due to destruction of rennin by hydroxyl ions, and was not dependent on any specific action of the sodium or potassium ion upon caseinogen or casein.—The geology of Samoa and the eruptions in Savaii: H. I. **Jensen**. The phenomena presented by the Savaiian volcano afford some clue to the direction in which to look for future developments in the forecasting of earthquakes and eruptions. The eruption in Savaii was due to a movement along the great structural line between Samoa and New Zealand which opened the fissure in 1902. The increase of folding consequent upon rise of the isogeotherms accompanying the sun-spot maximum of 1905 caused the re-melting of magmas at a depth, and squeezed them into the fissure, whence they have been escaping from several vents. The ingress of sea-water has had something to do with the eruption, as shown by the hydrochloric acid evolved, and it should be

mentioned that the rainy season, January to March, was that of greatest activity Many points of resemblance between Samoan and Hawaiian lavas command attention —Sand-movement on the New South Wales coast G H **Halligan.** The principal factors which govern the movement of sand and shingle on the littoral being ocean and tidal currents wave action and wind, the following matters are discussed —the effects of strong and weak currents, counter currents, and currents due to tidal flow upon the direction and rate of sand-travel, the movement of beach material due to tidal current a negligible quantity, sand-movement more pronounced during flood tide as compared with ebb tide a projecting headland may cause a current on its northern or southern side according as its northern side is concave or convex or whether the headland is at right angles to the course of the current, or meets it at an angle, the influence of the prevailing and the dominant winds upon sand travel as shown by an analysis of the winds recorded at Sydney during the decade 1894–1903, and at the Clarence River from March 1877, to August 1886 the manner in which sand and shingle are moved by wave action and by currents and the reasons why the sand on the coast of New South Wales is more readily moved to the south than to the north, where strong eddy currents do not exist, predominant influence of the strong southerly winds on the movement of sand above the limit of wave action, with instances of the northerly movement of sand-dunes on the coast The minerals and genesis of the veins and "Schlieren" traversing the aegirine syenite in the Bowral quarries D **Mawson** The veins ordinarily occupy fissures which may be very local, extending only a few inches, or at other times continuous by the establishment of connections between minor openings They are classified as (1) veins of bitumen distilled from the underlying Coal-measures, (2) simple pegmatite veins of (*a*) small and (*b*) of larger dimensions, which have originated by sweating from the sides, or by the residual gaseous and more liquid contents of the solidifying rock collecting largely in the same fashion and crystallising out as a coarse-grained product, and (3) veins exhibiting well marked flow structure and of finer grain more nearly related to the aplites —The fixation of nitrogen by *Azotobacter chroococcum* Dr R **Greig-Smith** Azotobacter is a slime forming microorganism and in combination with other bacteria, such as *Bact radiobacter* and *Bact levaniformans* with which it appears to associate it quickly produces a luxuriant growth of slime on saccharine media There is also a fixation of nitrogen, but this, as has been pointed out by Beijerinck and v Delden, is caused by Azotobacter, and not by the other bacteria, which however, may render assistance The fixation of nitrogen by *Rhizobium leguminosarum* Dr R **Greig-Smith** The investigation showed that races of the nodule former can fix atmospheric nitrogen in artificial culture and that the fixation is coincident with and proportional to the formation of slime Under conditions which assist cell growth, but which preclude the formation of slime, there is no fixation, and conversely, under conditions which assist the formation such as the presence of another bacterium there is an increased fixation

CAPE TOWN

South African Philosophical Society October 31 — Dr J C Beattie president in the chair —A series of mounted Cape Alcyonaria (Cœlenterates) obtained by the Government Biological Department J Stuart **Thomson** The specimens exhibited were of remarkable beauty in form and colouring One of the most interesting of the forms exhibited was *Anthoptilum thomsoni*, a colony measuring about 3 feet long and occurring in abundance at certain places probably forming miniature animal forests at the bottom of the sea —Connection between the rainfall at Durban and at Mauritius T F **Claxton** The note arises out of an inquiry into the possibility of seasonal weather forecasts for Mauritius Examination shows that the monthly departures from average of the various meteorological elements at Durban have no connection with those at Mauritius It appears, however, that winter droughts in Durban have invariably been followed by summer droughts in Mauritius at intervals of from three to seven months, and that prolonged droughts in Natal or those commencing in the summer may be either accompanied or followed by prolonged droughts in Mauritius There is some evidence to show that the interval depends upon the time of commencement of the drought at Durban —Discussion of the errors of certain types of minimum spirit thermometers in use at the Royal Alfred Observatory, Mauritius A **Walter.** The conclusions arrived at are —(1) the minimum thermometers (even the so-called "sensitive") should never be used as ordinary thermometers, (2) the errors from comparisons at certain temperatures may be as much as 2°, (3) the absolute minima obtained with the spherical bulb thermometers may amount to as much as +3° —The chemical composition of berry wax Dr B **van der Riet.** In this paper the author drew a comparison between constants found for berry wax (from berries of *Myrica cordifolia*) and those quoted for myrtle wax (from berries of various species of Myrica), by Dr J Lewkowitsch in his treatise on the chemical analysis of oils fats and waxes

THE THEORY OF AGGREGATES

The Theory of Sets of Points By W H Young and G C Young Pp xii+316 (Cambridge University Press, 1906) Price 12s net

CONDESCENDING to a pun, Gauss once remarked that he was more interested in notions than in notations. The theory of aggregates is so independent of the ordinary symbolism of mathematics that it requires hardly any previous acquaintance with other branches of the science from those who proceed to the study of it At the same time it is full of peculiar difficulties it abounds in seeming paradoxes and some of its fundamental problems are at the present time the subject of keen research and controversy A hearty welcome is therefore due to a work composed by authors who are familiar with all that has been published about aggregates and have themselves made important contributions to the subject

It is impossible to go into detailed criticism of this treatise without the use of technical terms which would convey no meaning to the ordinary reader, but an attempt may be made to show the general nature of this novel theory and the influence it has had and will extend, over the first principles of other parts of mathematics

The names of Cantor and Dedekind will always be associated with the first truly logical definition of the arithmetical continuum, or, which comes to the same thing of the range of a real arithmetical variable It is hardly possible to lay too much emphasis on the fact that all strictly arithmetical operations are connected with the elements (rational and irrational) of this continuum Cantor's transcendental numbers obey laws of operation different from those of ordinary arithmetic and the calculus associated with them ought to have another name

With the help of a postulate the necessity of which was first realised by Cantor and Dedekind we can establish a one one correspondence between the values of a real positive variable and the points of a finite straight line exclusive of one end if the variable is not allowed to be infinite If we extend the postulate so as to include both ends of the segment we have to include values 0 and ∞ for the variable, which from this point of view are equally definite For convenience we speak of a point x instead of saying "a point corresponding to the number x"

From the arithmetical side we have to investigate the properties of the continuum and of its parts, and the special interest of the subject begins when we consider parts which contain more than a finite set of elements The simplest of these is the natural scale 1, 2, 3 &c, its characteristic properties are that it has a natural order with a first element each element being succeeded by the next higher in magnitude and there being no last element

The set of rational numbers differs from the natural scale in some very important respects As represented by points on a line they have an order of position, corresponding to their order of size, but we cannot say that in this order any element is followed by a "next" element In fact between any two distinct rational points lie an infinite set of other rational points But Cantor was the first to point out that the rational set may be brought into a one one correspondence with the natural scale for example in the order —

$$\tfrac{1}{1}\ \tfrac{2}{1}\ \tfrac{1}{2}\ \tfrac{3}{1}\ \tfrac{1}{3}\ \tfrac{4}{1}\ \tfrac{3}{2}\ \tfrac{2}{3}\ \&c$$

where the fractions in their lowest terms are arranged so that the sum of numerator and denominator never diminishes while those with the same sum are placed in descending order of magnitude Every set which can be thus brought into correspondence with the natural scale is said to be countably infinite or to be of potency a Examples of such sets are (1) the set of all algebraic numbers (2) all points with rational coordinates in a space of n dimensions where n is any assigned positive integer

On the other hand the arithmetical continuum is not countably infinite and its potency denoted by c is of a higher order than a One of the outstanding difficulties of the subject is the question whether any set exists with a potency between a and c The most important theorem in this connection is that every perfect set is of potency c (p 234) A remarkable illustration of this is that all the points within a sphere may be brought into one one correspondence with the points on a definite straight line As might be expected the correspondence is not continuous

One of the most troublesome questions discussed in this volume is that of Cantor's potency aleph-one (p 135) Here we have a set the elements of which are sets of points the element sets recur over and over again *qua* sets and are treated as being all distinct in virtue of a criterion of order connected with a process of derivation and deduction Bernstein hopes to show that $\aleph_1 = c$

The potency of an infinite set is analogous to the number of elements in a finite set Cantor introduces symbols for potencies calls them transfinite cardinal numbers and investigates a calculus for them As pointed out on p 150 there is still a difficulty in the way of establishing comparisons between potencies really corresponding to comparisons of size between finite numbers and in any case the calculus of transfinite cardinals must greatly differ from ordinary arithmetic

Besides these ideas of order and potency, which are discussed in chapters i-v vi xi there is the additional one of content which dominates most of the rest of the book It must suffice to give a few illustrations to show the general nature of these inquiries If on a line of finite length l we construct an infinite set of non overlapping segments their content that is the sum of their lengths cannot exceed l If it is less than l, there may be left over a set of complementary segments but this is not necessarily the case as is shown by the example on p 78 Here we have a set of segments whose content is less than 0 2 of the original line yet no segment exists on the line which does not lie wholly or in part within one of the selected set The points not within any of

the selected intervals form a set of potency c. Similar theorems apply to areas and volumes: thus, if we take a unit square it is possible to "black out" a definite region within it, the area of which may be less than any *given* quantity, in such a way that no circle, however small, can be placed within the square without covering some at least of the black region, and so that the points not within the black region form a set of potency c. It should be specially noticed that although the black region is, or may most conveniently be constructed by an infinite process, it is perfectly definite, in the sense that we can say whether any given point (x, y) lies within it or not.

Another point to which attention may be called is the definition of "curve" (p. 219) as a set of points having certain properties. This is quite distinct from the idea of a path traced by a continuously moving point, and leads to very curious and interesting problems relating to rectification and quadrature.

Enough has been said to show how interesting and novel are the contents of this treatise; the examples and figures are of great help in making the general arguments intelligible, and the bibliography will enable the reader to consult all the literature relating to the subject. Finally, the appendix should not be overlooked, as it contains some important additional matter, besides a few corrections. To the latter may be added "chap. iv., § 20" instead of "chap. iv., § 3" on p. 77.

G. B. M.

METAMORPHOSES OF PLANTS.

Jugendform und Blütenreife im Pflanzenreich. By Dr. L. Diels. Pp. 130, with 30 illustrations in text, each with several figures. (Berlin: Gebrüder Borntraeger, 1906.) Price 3.80 marks.

IN this work the author has presented much interesting information from the point of view of an inquiry into the relations between sexual maturity and the conditions attained by the vegetative organs, especially where these from any cause show tendencies to marked changes of aspect during the development of the plants. Many of his examples are drawn from his personal investigations, the inquiry having suggested itself to him during a residence in Western Australia, where peculiarities in these relations appear to be remarkably frequent, and to be often traceable to the environment. He has also made a careful study of such published works as bear on this subject, and has used the materials derived from them with good effect as regards both the facts and the causes of abnormal conditions, and the inferences to be drawn from them. His statement of the whole subject, and of the conclusions that he believes can be fairly based on what is yet known of it, is well and clearly put, and shows the need of further inquiry, as well as the risk of pressing inferences beyond their fair limits at times.

The book is deserving of attentive perusal, and will suggest to the careful reader parallels among our own plants to some of the cases described, and questions in need of investigation from the new standpoint. The book opens with a discussion of the conditions that favour the attainment of sexual maturity in the normal course of development, and also prematurely, as measured by the stage of development of the vegetative organs. By selected examples it is shown how variable are the stages of progress, when judged by the leaves especially, at which sexual reproduction may occur. Attention is also directed to the assemblages of different species that exist on dry, poor soil and that are distinguished by the production of precocious flowers and fruits on ill-nourished dwarfs, as well as to the production of flowers in cultivated seedlings of various trees, as in the *Swietenia Mahagoni*, recorded by Mr. Hemsley (Hooker's "Icon." 2786), where deficiency of water appears to be the exciting cause.

The unusual precocity of reproduction is most evident where there is naturally a succession of leaf-forms before the normal period of flowering is reached, some of these being regarded as characteristic of the immature, and others of the adult plant. For the definite grades in such a succession Dr. Diels employs the term "Helikomorphie," the whole being included in the "Heteroblastie" of varied forms of parts having the same morphological value. The significance of the helicomorphies, where not of the grade usually associated with flowering, is shown to differ in different plants. In some even those characteristic of the normal immature plant may not be fully exhibited. In others these may be fully shown, but those of the adult may remain undeveloped or arrested. The causes that lead to such departures from the usual course can be shown to lie in the environment in some cases, but in others they cannot yet be explained. Among the more frequent causes of arrest and retention of immature characteristics are influences that interfere with growth, such as deficiency of water in dry soils, inclement weather at high elevations, shading and overcrowding, the plants grown under such conditions showing an unusual tendency to flower while having leaf-organs of the normal immature grade.

A comparison of allied species shows that the normal youthful helicomorphy of one may be very similar to the normal adult condition of another that lives in less favourable surroundings, *e.g.* in *Ranunculus sceleratus* and *R. pygmaeus*.

The importance of a thorough comprehension of these variations, of their significance in the life of each species, and of their value as indications of relationships between species or larger groups in classification, is self-evident. Embryology has not afforded like help in systematic botany to that obtained from it in zoology. In some cases seedling plants for a brief time show characters very unlike the adults and suggestive of the structure of less modified allied forms, as in the well-known examples of Ulex and Acacia. All such deserve careful study, and Dr. Diels has shown how they throw light on the value of "species," as in the forms of Limosella, and of "genera," as in the relation of Regnellidium to Marsilia. His discussion of the relations of certain species of Hakea, of Grevillea, and of numerous others, largely on the basis of his personal observa-

tions on the plants in their native habitats, is of great interest. The "larval" forms habitually passed through by certain plants, e.g., by *Veronica epacridea*, Actinostrobus, sps., and other conifers, various Leguminosæ, Eucalyptus, sps., Aloineæ, and members of other groups, are also discussed, and the conditions under which sexual reproduction may occur in plants that retain their larval aspect are investigated. That such plants have been described and named as distinct from the usual adult forms is well known, and this is seen to have been the case in Eucalyptus and in other groups.

A chapter on the phylogenetic significance of helicomorphy sums up the conclusions of the author. Many of the forms he regards as adaptations to environment, some of which are unstable, while others show the influence of heredity and persist under new conditions, e.g., the formation of phyllodes by Acacias in greenhouses. Some appear to become relatively constant in a short time, e.g., seasonal dimorphism of *Euphrasia Rostkoviana* and *E. montana*, believed by Wettstein to have become fixed as the result of the alpine meadows being mowed, and now retained in cultivation in a botanic garden. But, while there may in some be a strong hereditary tendency to repetition of the cycle, Diels concludes that each helicomorphic stage may be the starting-point of a new phylogeny. He emphatically opposes the belief that the helicomorphy of the immature plant necessarily represents a condition similar to that of the ancestors, and asserts that the apparently ancestral form has in many cases been acquired in response to the environments of the young plant. *Acacia insolita* is quoted as an example of a species descended from phyllode-bearers that now habitually produces pinnate leaves abundantly when mature, and the position is briefly stated thus:—"We saw that Phylloglossum resembles the young of many species of Lycopodium. But Lycopodium does not for that reason follow Phylloglossum in phylogeny, Phylloglossum may just as well be younger than the greater number of the Lycopods." The assumption that the infantile form must in all circumstances represent an older stage of ancestry than does the adult is frequently in opposition to the facts. A brief review of similar phenomena in the animal world, and a short bibliography, conclude the book. It only remains to add that the illustrations are excellent, and that a good index makes reference easy to the stores of information.

THE RADIO-ACTIVE PEDIGREE.

Radio-active Transformations. By Prof. E. Rutherford, F.R.S. Pp. 287. (London: Constable and Co., Ltd., 1906.) Price 16s. net.

THIS work is, in the main, a reproduction of Prof. Rutherford's Silliman lectures, delivered at Yale in March, 1905, and represents his latest views on the subject. Some treatment of radio-activity in general is given, and then a detailed development of the special subject of the book. This treatment differs only from the author's previous expositions in the greater detail in which the subject is worked out. Every month seems now to bring to light some hitherto unrecognised stage in the transformation of one of the radio-elements. One would suppose, however, that this field of discovery cannot be of unlimited extent, and that the full detail of the transformations must, before long, be made out, so far at least as they are accompanied by demonstrable radio-activity.

It has been usually assumed that each radio-active atom throws off an α particle, and becomes thereby transformed into an atom of a new product. On this view, it can be seen, with a little thought, that a mineral in radio-active equilibrium ought to owe an equal proportion of its activity to each of the products of a series, and there is considerable evidence that it is often so. Lately, however, two cases have presented themselves which seem clearly inconsistent with this. One of them, that of actinium, is mentioned by Prof. Rutherford in the present work. It seems that actinium, like radium, is found in uranium minerals, and in those only. Further, that the amount of actinium is probably, as the amount of radium is certainly, proportional to the uranium content. If so, we cannot but conclude that actinium is a member of the uranium series. Now comes the difficulty. Actinium certainly does *not* contribute anything like so much to the total activity of pitchblende as radium and uranium each do.

The second case is to be found in a paper in the October *Philosophical Magazine*. Moore and Schlundt have found that uranium X, the immediate product of uranium, gives a small α radiation as well as the β radiation by which it is mainly characterised. It is certain, however, that the α radiation of uranium is not much diminished by removing all the uranium X from it, hence the α radiation of uranium X must be comparatively small. Here again the principle of equal activity in each successive product of a series is violated. This latter case has only been brought to light since the publication of the present work, and quite a new light has been shed on the case of actinium by Dr. Boltwood's letter to NATURE describing the formation of radium from actinium. This seems to make it certain that actinium is in the main line of radio-active descent, and to put out of court Rutherford's plausible suggestion that it is the head of a collateral family. The subject, indeed, progresses so fast that the reviewer of a book like this almost always has lights which were not available to the author at the time of going to press.

The subject of the possible ultimate production of lead by the radium series is here discussed in some detail. It is doubtful, I think, whether much stress should be laid on the almost invariable presence of lead in uranium-radium minerals. An interesting spectroscopic investigation by Hartley and Ramage (*Engineering*, September 24, 1897) proved that lead was present in almost every one of a very large collection of iron ores examined by them. We cannot suspect a change akin to radio-activity in this case, for lead has a much larger atomic weight than iron,

and cannot be supposed to be a product of its disintegration

It is not necessary to dwell on the admirable lucidity and suggestiveness of Prof Rutherford's book, for that is no more than his readers have been taught to expect The only doubt which can be felt is whether it meets any want which was not already satisfied by his previous work, "Radio activity"

R J STRUTT

VISIBLE SPEECH

Lectures upon the Mechanism of Speech By Alexander Graham Bell Reprinted from the Proceedings of the First Summer Meeting of the American Association to Promote the Teaching of Speech to the Deaf, Pp 129 (New York and London Funk and Wagnall's Company, 1906) Price 1 00 dollar net

THIS interesting book consists of a series of lectures by Mr Alexander Graham Bell, whose name in the future may be as honourably associated with his labours in the education of deaf mutes as with the invention of the telephone His father, A Melville Bell, many years ago, devised a method of representing, or rather symbolising, positions of the vocal organs To this symbolic method he gave the name of "visible speech," because anyone acquainted with the symbols could place his vocal organs in the desired positions, and then, on emitting the breath and bringing the vocal cords into action, could produce the desired sound

"These symbols of visible speech," remarks Mr Bell, "bear the same relation to phonetics that chemical symbols do to the science of chemistry In dealing with the mechanism of speech, it is as necessary nowadays to make use of my father's symbols, as it is to use chemical symbols in treating of the composition of matter"

The symbols, which are very simple and ingenious, indicate the position of the lips, the position of the tongue, the condition of the larynx, and the condition of the passage between the larynx and the tongue or lips It is evident that to produce a given sound we might have a row of such symbols Thus, to sound the vowel *oo*, at least three position symbols would be required, and to show how to pronounce the word *moon* would require nine symbols, namely, three for *m*, three for *oo*, and three for *n* To avoid this difficulty the signs or symbols are abbreviated or condensed, so that the word *moon* is now represented by only three symbols, curious looking things, like old Gothic letters, but quite intelligible when one has, as it were, already studied their evolution The only comment I would make on the abbreviated symbols is that they should be printed on a fairly large scale, as a very slight mark may be of great importance, and a sharp eye is required if the symbols are printed small

Mr Bell then proceeds to show how the meaning of the symbols may be conveyed to the deaf They are exhibited on a large scale in a series of charts, and with infinite patience the teacher enables, by gestures and movements, the deaf mute to comprehend their meaning Step by step the pupil is taught how to place the lips, the tongue, the soft palate, and how to modify the form of the mouth The child has also explained how to produce various vowel sounds, which are divided by Mr. Bell into primary vowels, wide vowels, primary round vowels, and wide round vowels Each of these is accompanied by a symbol To show how much may be symbolised, take three of the primary round vowels, and we have symbols indicating (1) voice, back small aperture, lip small aperture, (2) voice, back mid aperture, lip mid aperture, (3) voice, back large aperture, lip large aperture

The teacher must have a feeling of great delight when he hears for the first time the required sound coming from the mouth of the deaf mute. Mr. Bell's criticism of methods is both wise and interesting, as we show by the following quotation —

"Now in teaching a deaf child you present to him a symbol for some difficult sound If he has been taught to analyse the symbols in the manner shown, the symbol conveys to his mind a direction what to do with his mouth That is what your pupil has to aim at, but in ninety nine cases out of a hundred he may not get it, at least at the first shot Now what are you going to do? Are you going to say, 'No, no! that's not right Try again'! Let him try once more, and the chances are that he fails again to give the sound intended The no-no method only aggravates the difficulty by discouraging the pupil and disgusting him with articulation The deaf child must know *what he did when he failed* The knowledge of that realism will guide him in his next attempt For example —If he knows that his tongue was too far forward in the mouth, in his next attempt he aims at having his tongue further back, and probably gets too far in that direction If, then, he is told the result of this attempt also, he makes due allowance the next time he tries He may fail a hundred times Now the position may be a little too far forward, now a little too far back, or the tongue may be too high or too low, but his knowledge of the effect of each effort causes him to approach more and more closely to the exact position desired, till at last he gets it, The time spent in studying and representing the incorrect positions is not wasted, for it gives the pupil mastery over the instrument of speech itself, and the struggle to get exactitude of position with one difficult sound gives him power to get any other, just as the ability to hit one bull's-eye qualifies a man to shoot at any mark" (p 70).

These wise remarks apply to many methods of practical instruction, in the laboratory and elsewhere Mr. Bell's lectures were delivered to teachers of deaf mutes, and often at the close of a lecture Mr. Bell was interrogated This Socratic method drew from the teacher many valuable remarks, and sometimes "asides," which showed the fertility of the lecturer's thought Altogether this little book is full of interest to students of phonetics, a department of science often a wilderness of dreary discussion, but here, in the hands of Mr Bell, a subject of living interest. To be able to teach deaf mutes how to communicate with their fellow mortals is an achievement worthy of one who has, in another province, made his mark on the technical science of the day

JOHN G McKENDRICK

THE GEOLOGY OF ARMENIA

A Treatise on the Geology of Armenia. By Dr Felix Oswald. Pp vii+516 (Iona, Beeston, Notts.: Published by the Author, 1906.) Price 1l 1s net.

THIS is a remarkable book from the point of view of the mere collector, and, in all seriousness, libraries should hasten to secure it. It has been hand-printed by the author, page by page, almost in the Caxtonian manner, and we are informed in a manuscript note that only 100 copies exist. That it was printed at all is due in the first instance to the rather stringent requirements of the University of London, to which it was presented as a thesis. It served its purpose there, but obviously deserved a wider circulation. It now appears with numerous hand-printed and hand-coloured geological sections, and some expressive, but not equally necessary, plates of fossils. The result is a book which is typographically a pleasure to read, each page being firmly printed in letters which are really black, and the hard travelling which lies at the back of its production is almost equalled by the subsequent and skilful industry of the author.

Dr Oswald's work should stand on shelves of reference beside Mr H. F. B. Lynch's fine volumes on Armenia, since the geological observations on which it is based were made when the two authors travelled together through a region of immense geographical and historic interest. About half the book describes Dr Oswald's own original results, and the remainder contains a valuable review of what has been previously written on the geology of Armenia. It is clear that we have here an unusually full work of reference, and the author-compositor has not shrunk from completing it by an index of sixteen pages.

The mountain-folding that determines the structure of Armenia (p. 9) seems to have occurred in Lower Permian, ante-Tithonian, and post-Oligocene epochs. The pressure in each case came from the south—Dr Oswald writes "resultant pressure," which we presume refers to the resultant of various forces within the crust. "The northern limit to all this mountain-folding was formed by the great granitic '*horst*' of the Meschic Mountains." The Caucasus is held to owe its present development to post-Miocene pressure from the north-east, which broke up the Armenian sediments into blocks. While Prof. Penck in a recent publication prefers to regard such blocks as the result of vertical forces, Dr Oswald sees in them (p. 10) "as much an expression of the tangential stresses in the earth's crust as the folds of the Caucasus itself." The volcanoes of Armenia have arisen along the post-Miocene lines of fracture, and the larger ones occur at points of intersection.

The most striking contribution of the author to our geological knowledge is the account of the Nimrud volcano (chapter ix.), the first survey of which was made by him and Mr Lynch in 1898. We all may be grateful to the Vali of Bitlis, who caused fifty soldiers to encamp in the crater in order to keep off bandits during these scientific investigations. The crater is five miles across, and its rim rises four thousand feet above Lake Van. The account of its structure and petrography is thus by itself no mean achievement.

The existence of Mr Lynch's book has left the present author little scope for picturesque description, but one landscape at least (p. 252) is brought vividly before us, where the broad dioritic downs of Kazikly Dagh end suddenly in "precipices seamed by torrents," and the country drops 5000 feet in four miles to the Meiriman Dereh.

Dr Oswald's review of preceding literature contains many useful criticisms and suggestions (pp. 355 and 356, for example). The book is not intended to be read from cover to cover as a narrative of travel, but it should obviously be made accessible to all future travellers in Armenia. G. A. J. C.

OUR BOOK SHELF

Position-line Star Tables for Fixing Ship's Position by Reduction to Meridian and Prime Vertical without Logarithmic Calculation. By H. B. Goodwin, R.N. Pp. xiv+96. (London: J. D. Potter, 1906.)

THERE are several tables in use which will enable a mariner to derive the correct meridian altitude of an object when the altitude near the meridian is known. Mr H. B. Goodwin has constructed tables which will give a correction of a similar character to obtain from observed altitudes near the prime vertical the correct altitude on that circle. If the object does not cross the prime vertical, the author employs the circle of maximum azimuth. The tables are not general, but refer to certain bright stars, eleven in the northern and six in the southern hemisphere. Seeing that some of the declinations fall very close together, as those of α Andromedæ, Pollux, α Coronæ, &c., there might have been some advantage in computing the tables for regular intervals of declination rather than for selected stars.

It is not difficult to derive a system of corrections which give the corrected altitude on the prime vertical, but are such tables necessary? The problem is to derive most readily the hour angle from an observed altitude of a known object in a given latitude. The advantage of referring the object to the prime vertical is not equally apparent, but the object of the author in a great measure is to avoid logarithmic calculation. This he has effected, and his arrangement is apparently convenient and sound from the analytical point of view. But if the suppression of logs is to necessitate such multiplication as 303.2×2.97 and 418.4×3.23 (numbers taken from the examples given), it is hard to see what improvement has been made.

We have worked out some of the examples both by means of these tables and also by solving the ordinary triangle ZPS. We have no hesitation in preferring the old-fashioned method. But we admit it requires great familiarity with tables before their full value is appreciated, and possibly anyone who has given the same amount of study to these tables that the writer has been obliged to give to logs would prove the superiority of Mr Goodwin's tables. But some people seem positively mad on tables. Would any sane man or anyone who could work such a sum in decimals as that just quoted, use a table for converting seconds of time to the decimals of a minute? Yet such a table is given here, evidently with the idea that someone would use it to find out that 24 seconds was equal

to 0·4 of a minute. We suspect that Mr. Goodwin knows a good deal more about the capacity of the men for whom he is writing than we do.

W. F. P.

The Horticultural Note Book. Compiled by J. C. Newsham. Pp. xx+418. (London: Crosby Lockwood and Son, 1906.) Price 7s. 6d. net.

THE contents of this book are as disconnected as are the words in a dictionary. Anything like a "review" is, therefore, out of the question. We can only state the general nature of its contents and give an opinion as to the way in which the compiler has accomplished his task. As to its contents, they comprise "practical rules, data, and tables for the use of students, gardeners, nurserymen, and others interested in flower, fruit, and vegetable culture, or in the laying out and management of gardens."

This is a fairly comprehensive enumeration, but it is not complete, for we also find various tables which will be of service to those who have to deal with woodcraft or the sale of timber. The compiler has done his work well, he is evidently familiar with the ordinary requirements of his readers, and he has fulfilled them with judgment and accuracy.

With such a mass of detail to deal with it would be wonderful if misprints did not occur, but they are remarkably few. On p. 299 there is, however, a crop of such blemishes which should be removed in a future edition. We may suggest also that the tables on pp. 251, 252 be expunged as inadequate and in point of accuracy not equal to the rest of the volume. We are glad to see various metrical tables added. No one who compares the regular definite proportions of the metrical system with the confusion of the ordinary lineal and land measures, to take one instance, can doubt the advantages of regular system over chaos. It is permissible to envy the next generation, whose labours will be so materially lightened by the general adoption of the new system.

The author has given not a few "miscellaneous" weights and measures, but he might have added more from the Covent Garden repertory, where cabbages are sold by the "mat," carrots by the "pad," cauliflowers by the "tally," to say nothing of "bundles," "bunches," "cases," and other indeterminate measures. A book of this kind is intended for reference purposes, and its value must be tested by frequent consultation. Tried by this test, we may say that we have found the book very serviceable. In a future edition a list of the commoner fungi and the plants on which they are parasitic would be desirable, for instance, we find no reference either to the ordinary or the American mildew attacking gooseberries, or to the fungous pests which commit such havoc with grapes, tomatoes, and cucumbers.

Funzioni poliedriche e modulari. By G. Vivanti. Pp. viii+437. Manuali Hoepli, 366-367. (Milano: Ulrico Hoepli, 1906.) Price 3 lire.

THE author tells us in his preface that he found Klein's "Vorlesungen über das Ikosaeder" and Klein and Fricke's "Theorie der elliptischen Modulfunctionen" "pretty stiff reading." Probably most students will sympathise with him and will give a ready welcome to this little book, which is intended to prepare the reader for the study of these classical treatises. The ground covered is approximately that of the last four chapters of Forsyth's "Theory of Functions" (excluding automorphism), but the subject-matter is discussed in much greater detail. The first part of the book deals with groups formed by substitutions of the form $z' = (\alpha z+\beta) \div (\gamma z+\delta)$, especially with the five finite (polyhedral) types of group and with the infinite (modular) group in which α, β, γ, δ are integers such that $\alpha\delta - \beta\gamma = 1$. In the first few pages a group is defined and some of its more elementary properties proved. It must be confessed that these introductory sections are not quite satisfactory, and it is doubtful whether they would be readily intelligible to anyone who had no previous knowledge of group-theory. For instance, the author fails to make clear the distinction between a group and a semi-group, or that between an abstract group and the particular application he has in mind. The rest of part i. is, however, clear and readable, and should serve effectively the purpose intended by the author.

In the second half of the treatise the author discusses the invariants of the polyhedral and modular groups, the connection of the Schwarzian equation with polyhedral and modular equations, and the application of the polyhedral groups to the solution of algebraic equations. This part appeals to a very different class of readers, in fact, the author assumes a knowledge of elliptic functions, Riemann's surfaces, the existence theorem, Noether's curve, the Galois field theory, &c. The lack of balance between the two parts in this respect is unfortunate, if unavoidable. There are a few errors, for instance, the statement of § 104 seems to require modification when $n=6$, while on pp. 208 and 209 the difference between (n), $[n]$ and $\{n\}$ is not at all clear.

Hermann von Helmholtz. By Leo Koenigsberger. Translated by Frances A. Welby, with a preface by Lord Kelvin. Pp. xvii+440. (Oxford: Clarendon Press, 1906.) Price 16s. net.

THE German original of this book appeared in 1903, and was reviewed at some length in NATURE of July 2 in the same year (vol. lxviii., p. 193). The work of translation is admirably done in every way, and the English public owes a debt of gratitude to the translator for enabling it to study in its own language one of the most interesting careers of the nineteenth century. A moderate all-round scientific training is necessary and sufficient to enable the reader to follow the description of the greater part of Helmholtz's work, but, though mathematical symbols are avoided, probably no one who has not specialised to some extent in applied mathematics will find intelligible the account of his more abstruse mathematical researches.

Though Herr Koenigsberger makes the very most of the space at his disposal, yet the reader lays aside a book of 440 pages with a feeling that he has seen the merest sketch of Helmholtz's life. Probably no better comment could be made on the industry of the great man of science or on the versatility of his genius. To do full justice to his career a treatise of three times the length would perhaps be needed. As it is, the reader is bewildered at the rapidity with which his attention is turned from one epoch-making discovery to another, and tries in vain to follow the steps by which Helmholtz was led from one subject to another when, during the space of three years largely occupied with his professorial duties, he discussed in turn optics, nerve transmission, acoustics, hydrodynamics, geometry, electricity, hay-fever, and so on.

Though, on the whole, the book lays more stress on Helmholtz's work than on the details of personal interest, yet the author has a true instinct for recording just those incidents of Helmholtz's life which throw most light on his character and ideals, and reveal most clearly the influences which surrounded him. We lay down the book with a feeling of very real sympathy for the frequent illness and bereavement which cast a perpetual shadow over the plea-

sures of a happy home and world-wide reputation, while we are conscious of a genuine admiration for the firm resolve to "make the most of his time" and to keep perpetually before him the remembrance of "how injurious megalomania may be for a student"

H H

Illustriertes Handbuch der Laubholzkunde By C K Schneider Pts iii and v (Jena Gustav Fischer, 1906) Price 4 marks each

THE general plan of this handbook or trees cultivated in Europe was explained in the notice of the first two parts that appeared in NATURE, November 24, 1904. The third part was issued early last year, and the fifth part—somewhat enlarged—completes the first volume

The third part contains the final portion of the Berberidaceæ, the orders Menispermaceæ to Crassulaceæ, and part of the Saxifragaceæ, the largest genera being Berberis, Mahonia, Magnolia, and Ribes. The Drupaceæ and Pomaceæ, generally regarded as suborders of the Rosaceæ, here treated as orders form the subject of the fifth part Prunus, Padus Pyrus, Sorbus, and Cratægus are large and difficult genera

It becomes more apparent that Dr Schneider favours subdivision, for, in addition to the suborders mentioned, subgenera such as Chænomeles are raised to generic rank, and some of the species would certainly be regarded by other authorities as varieties, also it is noticeable that the author does not confine himself to trees in cultivation The book thus becomes more of a dictionary and less of a practical manual, but due credit must be given to the author for the enormous amount of energy expended, and for the searching and critical investigation of specimens that has been accomplished The advantage of the rules laid down at Vienna last year becomes evident from the list of changes noted in the supplement

Old-fashioned Flowers and other Open-air Essays By Maurice Maeterlinck Translated by A Teixeira de Mattos With illustrations by G S Elgood Pp viii+115 (London George Allen 1906) Price 3s 6d net

PUBLISHERS have to cater for readers of various tastes, and so we suppose there are some to whom the present little book will appeal For ourselves we can but wonder that anybody thought it worth translating The text is mostly purely rhapsodical, reminding us of Ruskin at his worst There is very little said about flowers as flowers, and the moral and philosophical reflections present no striking novelty The illustrations are attractive but over-coloured, and probably do not do justice to the artist's original drawings

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The January Meteors

THE January meteors are seldom visible in England under favourable aspects, the weather being often adverse at this season Moonlight will partly veil the display in 1907 and the best times to look for it will be on the evenings of January 3 and 4 during the two or three hours preceding moonrise

The shower is sometimes as rich as an ordinary return of Perseids, and it always furnishes some bright, long meteors of an unusually conspicuous character We have gathered a large number of double observations of Perseids and Leonids, and know their average heights very well, but very few real paths of the January Bootids (or Quadrantids) have ever been computed It is desirable, therefore, that observers who are fortunate enough to notice any members of the latter shower should record their apparent paths with the greatest accuracy which the circumstances allow, with the view of finding their heights and radiants

The position of the radiant point has been already well determined at 230°+53°, and it is not probable that we shall ascertain it more precisely until photography can effectively take the place of the eye in meteoric observation

W F DENNING

Stereoscopic Lantern Slides

PROBABLY many people who have taken interest in stereoscopic photography at one time or another have regretted that there should be no simple means for showing the effect to a large audience

As a matter of fact this can be done very easily in either of two ways A stereoscopic lantern slide is first made by photographing an ordinary stereoscopic pair of pictures This pair of pictures is then projected upon the screen with an ordinary lantern The stereoscopic effect is obtained by using either a mirror stereoscope or a prism stereoscope The former consists of two small pieces of mirror held one in front of each eye The observer has the screen not in front of him but on one side, say about 60° from the direction in which he is facing

In each mirror the pair of pictures is seen and by tilting one mirror with respect to the other so that the two outside images are superposed the picture suddenly leaps into relief Of course if the wrong pair be superposed the familiar inverted relief will appear It is easy to mount the mirrors in a sort of spectacle frame one of them being fixed and the other capable of rotation about a vertical axis

It would not be difficult to explain to an audience of average intelligence the method of using such spectacles the spectacles could be made at a very small cost and the beauty of the effect would appeal to many

Cases frequently arise in university lectures in which a stereoscopic presentation of slides would greatly simplify explanations *e g* in biology

The other method is to use a single small achromatic prism, which is held in front of one eye the refracting angle being vertical and directed towards the other eye Of course prisms of different angles are required for different distances but a single prism can be made to suffice for a large range by twisting it about a vertical axis without greatly impairing the "stereoscopism"

At first sight one might think that the effect could only be seen by observers situate in or near a plane bisecting the screen at right angles but this is not the case Indeed, anyone who has worked with stereoscopic photographs must have been struck with the ease with which the eyes will adjust themselves to pictures which are not correctly aligned and experiment also shows that the two pictures need not be of the same size

The University, Birmingham December 17

Emerald Green Sky Colour

WHILE on a short stay at St Moritz I was much struck by the peculiar colour of the sky on the evening of December 10 It had been threatening snow most of the day and a few flakes fell during the afternoon, the sky being overcast At about 3 30 p m to 4 p m the sky cleared over the mountains towards the east and revealed instead of the usual blue, a fairly large expanse of vivid emerald green None of us had ever seen it before so that we all stopped I should be much pleased if any of the readers of NATURE could give me some idea of the cause of this unusual phenomenon

J W NOLTE

Kurhaus Lenzerheide, St Moritz, December 18

THE FRENCH SAHARA

(1) M. FOUREAU has already told in a popular form the story of the expedition which he conducted with so much skill and success from the shores of the Mediterranean to the mouth of the Congo. Crossing the little known country of the Touaregs, making the circuit round Lake Chad, descending the Shira and Ubangi Rivers, he had ample opportunity for examining the French possessions in Africa and studying the prospects of their future development. During the six years that have elapsed since his return from this expedition he has been engaged in arranging and discussing the scientific results, some of which[1] are now presented to the public. The first and second fascicules give details of the astronomical and meteorological observations, with a description of the water systems, the topography of the district, and the geological action of local winds. It is fortunate that the atlas of maps, which are drawn on a very elaborate scale, accompanies these handsome volumes. Since the geography of this part of Africa is somewhat uncertain, these are necessary in order to follow the exact route taken by the expedition.

M. Foureau is well known as an African explorer. For nearly thirty years he has traversed the Sahara in all directions, but his ambition to penetrate to the Sudan has always been foiled by the action of the Touaregs. In his many expeditions he has naturally been assisted by the Government and by learned societies, but he has never had at his command a force sufficient to overawe this warlike tribe and to make himself independent of its assistance or good will. In 1898 by a fortunate accident he found himself placed in a more hopeful position. Through a legacy from M. Renoust des Orgeries to the Société de Géographie a considerable sum of money became available for the purposes of exploration. The object of this bequest was to assist such expeditions as were undertaken with the view of bringing the independent tribes in the interior of Africa under the influence or protection of France, and which should by pacific measures tend to weld into a homogeneous whole the French possessions extending from Algeria to the Senegal and Congo. These funds were placed at the disposition of M. Foureau, who found himself in the autumn of 1898 at Wargla at the head of a small army of some 300 men, a thousand camels, and the usual equipment of a well-organised expedition. M. Lamy, of the army of Algeria, was associated in the command of the expedition, and had charge of the military dispositions. Unfortunately this energetic officer and able colleague, whose very ready assistance is warmly acknowledged, lost his life in an encounter with the natives.

The astronomical observations would perhaps be more fittingly described as geodetical, since they are naturally limited to the determination of the position of stations. The observations were made by M. Foureau and Lieut. Chambrun. For his longitudes the former relied mainly on the methods used at sea, supplemented by a few occultations and phenomena of Jupiter's satellites. The author carried four available chronometers, and remarks that the error in longitude arising from the accumulated error in the rate of the chronometers during 102 days amounts to only seven minutes of arc. It is not quite clear how this seven minutes is reckoned, but it certainly implies excellent performance of the watches and great care in their manipulation. It should be added, too, that wherever a comparison between the longitudes derived by different methods is possible, the agreement is quite satisfactory. M. Chambrun trusted to equal altitudes of moon and stars, and transits of the moon across the meridian. The latter, like some of the lunar distances taken by M. Foureau, were not found to possess sufficient accuracy. For latitudes both observers measured the altitude of Polaris and meridian altitudes of sun and stars. These results call for no remark, though it is impossible not to admire the energy which enabled these observers to prosecute their work after the fatigues of hard travel. M. Foureau also made some measures of the magnetic declination and horizontal force.

The meteorological or climatic observations are particularly welcome. These observations are of course spread over a large area, and it is not the climate of any one district that is presented. Concerning temperature, the author remarks that the thermometer fell below zero (C.) twenty-five times, the minimum reading being −10°.2 (14° F.) at a height of 1144 metres. The highest temperature experienced was 48°.3 (119° F.) in March, 1900. Throughout the region the minimum temperature occurs about 5 a.m., and the maximum between 1 and 3 p.m. During the 645 days on which observations were possible the sky was entirely free from cloud on 132 days, slight cloud was noticed on 227, while the sky was more or less overcast on 286. Dew was noticed on fourteen occasions, and rain fell on 116 days, but of these only forty-six were marked by severe storms; but violent atmospheric effects, whether of wind or lightning or sandstorms, were of frequent occurrence. In the Aïr highlands, almost every afternoon the sky was blackened, while violent thunder and lightning were experienced. The entire horizon would be continuously illuminated during whole minutes by brilliant flashes of lightning. Sudden hurricanes and appalling outbursts would keep men and animals in a state of tense excitement. Slight friction on the manes and tails of horses would bring forth, not electric sparks merely, but "des nappes de lumière."

The description of the Grand Erg and the character of the country through which the expedition passed,

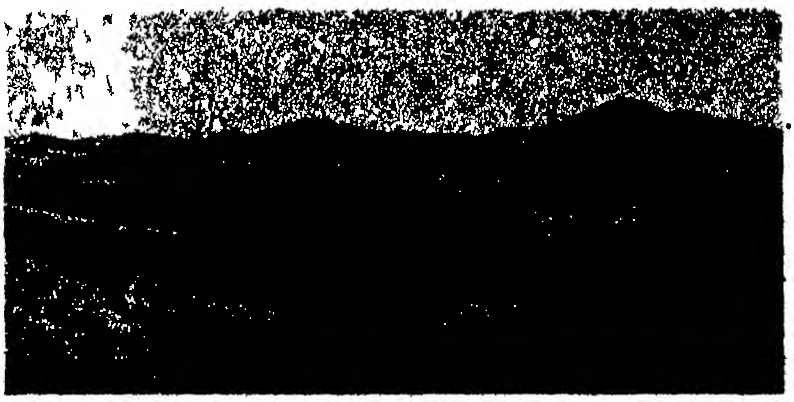

FIG. 1.—Large sand dunes in the Erg region, Sahara.

[1] "Documents scientifiques de la Mission saharienne (Mission Foureau-Lamy d'Alger au Congo par le Tchad)." By F. Foureau. (1) Parts i. and ii. Observations astronomiques et météorologiques. Pp. iv+551. (2) Part iii. Pp. 555–1210, with an atlas containing 16 maps. Geology, Petrography, Palæontology, &c. (Paris: Masson and Co., 1903–1905.)

its plateaux, its mountains, its profile, are all well brought before us; the illustrations are admirably reproduced, and the maps and plates make the text clear. Naturally M. Foureau had ample opportunity for studying the effect of wind erosion. On the Sahara its work is patent. The great variation in temperature by day and night brings about a constant cracking and crumbling of rocky corners, grinding each other into smaller fragments, which are ever being blown about by winds powerful enough to whirl along lumps of stone like feathers. Thus the constant manufacture of sand goes on, the friction of the particles of which gives to hard, compact rocks a polish like that of the lapidary's wheel. Other rocks of unequal consistency yield irregularly. The author traces the effects on various kinds of rock, granites and sandstone, and shows the fret and honeycombing that follow. Having produced the sand by hard wear and tear it is comparatively easy to construct the dunes, so conspicuous a feature on the comparatively level plains of the Sahara. Wherever obstructions intervene, such as prominent rocks, bushes, inequalities in the distribution of sand level, a steep talus of grains gathers in the sheltered lee, while a more gentle sloping bank gradually rises on the windward side of the obstruction until this is finally buried. The weird shapes into which this sand is blown, the strange curves it assumes, seem to be in many parts of the Grand Erg the only variation in a desolate landscape (Fig. 1). The author's description of Lake Chad is very interesting. This lake has about it something mysterious, and it is much to be regretted that the examination was not more thorough, with the view of unravelling what is obscure. To picture the lake as a compact sheet of water is quite inadequate. Whether the lake may be considered as containing an archipelago, or whether it runs away into numerous lagoons, creeks, swampy stretches, disconnected from the main body, is not yet cleared up. Whether these detached patches of water were originally parts of the lake and now represent the deepest portions of the original bed, indicating that the lake is gradually disappearing, is one of those problems upon which more information is required. In these detached lakelets the water is brackish, but in the main body of the lake the water is fresh. The author raises the point whether some of these separate lagoons are not fed by subterranean water, which might explain the presence of salt. Where communication with the lake is probable or suspected there is very little salt in the water, but where the two are clearly distinct the presence of salt is very pronounced in the smaller body. M. Foureau directs attention to some very interesting points concerning the currents in this lake or in extensions of it, and discusses whether these currents are due to wind or evaporation; but into this, as into many other important points examined in these volumes, we have not space to enter.

W. E. P.

(2) Now that so much new light has been thrown on North African geology by the explorations in the Lake region in the east on the one hand, and in the territories of Germany, France, Great Britain, and the Congo Free State in the west, the largest of the unexplored tracts left of the once "Dark Continent" is that of the French Sahara lying between Algeria on the north and the Congo territories on the south. Of this vast area a preliminary survey has been accomplished by the Mission Foureau-Lamy, which, setting out from Algeria in November 1898, reached the Congo by way of Lake Chad in July 1900. Ample collections were made along this almost unknown route, and detailed observations recorded on the topography, hydrology, and geology of the countries on the line of march. The results of the examination of the botanical, zoological, geological, and ethnological specimens in the light of observations made during the journey are now published by the Geographical Society of France, with the aid of subventions made by the French Government, the Academy, and the French Association for the Advancement of Science. Needless to say, the work before us (part iii.) has been issued in a form worthy of the highest traditions of French science, and with a great wealth of valuable illustrations.

Fig. 2.—Weathered pegmatite, showing the appearance of rock masses in the Sahara.

In the geological notes made by the travellers along the line of route are found many very interesting observations on the mode of weathering of rocks in tropical districts. The illustrations reproduced are excellent examples of the action of sun and wind upon rocks in a desert region. The rocks passed over consist of granite, which appears to occupy a very large area, crystalline schists, and sporadic masses of various volcanic rocks, with representatives of Silurian, Devonian, Carboniferous, and Cretaceous formations. In addition to these there are sandstones of which the geological age could not be determined, and various superficial deposits.

The rock specimens were entrusted to M. L. Gentil, of the Sorbonne, a pupil of Prof. Lacroix, for description, and his report on the petrography of the regions traversed is a contribution of great value. Interesting laterites, diatomaceous earths, and travertines are among the most important of the materials of aqueous origin. The igneous rocks exhibit a great variety, and include, besides many varieties of granite, ophitic diabases, andesites, rhyolites, trachytes, phonolites, tephrites, and basalts. One very interesting feature exhibited by many of these rocks is their richness in the alkalies—the soda augites and hornblendes, like riebeckite, ægerine, &c., abounding in them. These facts, taken in conjunction with the studies by Mr. Prior, of the British Museum, on the rocks of the Lake district of Africa, of Prof. Bonney on those of Socotra, and of Prof. Lacroix in the Somali country and Madagascar, lend support to the view enunciated by the last-mentioned geologist that

a belt of alkaline igneous rocks surrounds the African continent

The extensive collections of fossils brought home by the members of the Foureau-Lamy mission were placed in the hands of the late Prof. Munier-Chalmas for description, and on the lamented death of that palæontologist were transferred to his successor, Prof. Émile Haug. Valuable assistance in the work of determining and describing these fossils was received from Profs. Zeiller and Douvillé and from M. and Madame Œhlert. The result of these studies is to show that, in addition to the granitic and metamorphic rocks which at present cover such wide areas in the French Sahara, fossiliferous strata belonging to the Silurian, Devonian, Carboniferous, and Cretaceous systems also occur.

At a place called Tindesset, about 764 miles due south from Philippeville, there is found a series of

FIG. 3.—The larger specimens illustrate the fine fretted patterns produced on the surfaces of limestone rocks by the continued action of impinging sand grains driven by the wind. The four smaller specimens (17, 18, 19 and 20) illustrate the wearing down of fragments of siliceous rock, acted on by the natural "sand blast." These are similar to those described by Mr. Enys from New Zealand.

shales cropping out from below the Devonian sandstones. The point at which they occur is nearly 4000 feet above the sea, and was reached with great difficulty by the members of the expedition. On splitting specimens of these shales that were brought home the late Prof. Munier-Chalmas found undoubted examples of graptolites belonging to the genus Climacograptus. At that time strata of Silurian age were not certainly known to exist in the Sahara or in any part of northern Africa, but subsequently M. Flamand described graptolite shales as occurring in the Sahara at a locality about 250 miles north-west of Tindesset. As these belong to the Llandovery (Gothlandian) stage, the fossils of Tindesset may not improbably be referred to the same age.

The Devonian strata cover a wide area in the northern part of the district traversed by the mission. Strata of this age were recognised by Overweg so far back as 1850, the fossils being determined by Beyrich. In the district of Tassili they form a plateau consisting of sandstones passing into quartzites. Besides the obscure fossils referred to, Spirophyton, Arthrophycus, Nereites, Crossopodia, Nemertites, and Medusina, undoubted examples of Homalonotus, Melocrinus, and various brachiopods occur, which justify the placing of these strata at the very base of the Devonian. In addition to these, a number of separate valves of a lamellibranch shell, mineralised by hæmatite, were found. These are referred by Munier-Chalmas to a new genus (Desertella), and the beds containing them are doubtfully assigned to the Middle Devonian.

The Carboniferous system, also first recognised in North Africa by Overweg and Beyrich, has been found at many points in the Algerian Sahara, and a fairly large series of fossils (principally plants and brachiopods) was brought back by the members of this mission. The strata of sandstone and limestone appear to rest quite conformably upon the Devonian sandstones, and to represent low horizons in the Carboniferous system (Oural̈ian and Moscovian). As is well known, Upper Carboniferous strata also occur over considerable areas in North Africa.

The Cretaceous strata consist of the widely-spread beds of limestones forming extensive plateaux, and containing *Ostrea columba* with other characteristic Cenomanian fossils. The escarpments formed by these limestone plateaux have a height of from 300 feet to 350 feet, and at their base it has long been known that variegated clays with beds of gypsum occur. Up to the time of the dispatch of the Foureau-Lamy mission, however, no fossils had been found in these beds, and their age remained doubtful. The discovery of the remains of Cretaceous types of Ceratodus with other fishes and some reptilian bones led Munier-Chalmas to assign these strata to the same age as our Gault.

In addition to the fossiliferous rocks referred to above, tracts of sandstone strata, which yielded no trace of fossils, were found, and the exact geological age of these must remain for the present in doubt.

Two plates of the work are devoted to illustrations of the structures developed in limestone rocks by æolian action—the impinging on rock-surfaces of sand grains driven by the wind. These are well known to all geologists who have studied desert formations, but the examples so beautifully figured in this work are of exceptional interest (see Fig. 3).

In the ethnographical section of this volume, which is very full and admirably illustrated, facts of very considerable geological interest are recorded. Most important of these is the account of the occurrence of implements formed of sandstone and quartzite, which are of undoubted Palæolithic types. The whole of the ten examples appear to be of the large, elongated, and pointed form so common at Saint-Acheul, none of the smaller oval type having been found. Neolithic types of both polished and unpolished implements abound, and are very fully illustrated.

Both the authors and publishers of this very important work are to be heartily congratulated on the discoveries made and the manner in which they are given to the world.

J. W. J.

SCIENTIFIC WORK ON MONT BLANC[1]

THE sixth volume of these reports upon the observations made in the highest experimental station in Europe contains an account of some valuable results obtained by the director, M Vallot, as to the respiratory changes associated with prolonged residence at the altitude of 4350 metres The observations were begun at Chamonix in 1886, this preliminary inquiry led to extended experiments with improved methods mainly in 1898, 1899, and 1900 The object of the inquiry was to ascertain the physiological condition, as regards respiratory efficiency, of an individual living for some little time in the observatory and carrying on his ordinary avocations Many observations were made by M Vallot upon himself, but these were supplemented by those obtained from a skilled collaborateur, M de Goumoens

It cannot be said that this prolonged and laborious inquiry presents that extent of scope which was such a characteristic feature of the work carried out by Prof Zuntz, but the results are in some respects quite as valuable as those of Zuntz and his colleagues, for, in the first place, they are trustworthy observations made during a prolonged sojourn at an altitude exceeding that of the Margherita Cabin on Monte Rosa, and, in the second place, the fact that they are confined to one narrow field gives them an additional scientific exactitude It is undoubtedly an advantage, in any study of the exceedingly complex changes which the living organism undergoes at high altitudes, to focus the attention upon one point of fundamental importance It is obvious that such a point is the total respiratory ventilation during a stay in high altitudes, for the modification of the respiratory acts is a familiar incident in the experience of all those who have had the opportunity of reaching the summit of the higher Alps Moreover, the detailed study of respiratory modification through diminished atmospheric pressure must be carried out before drawing any physiological conclusions as to the significance of those general metabolic changes which have been so ably brought forward by Zuntz There is consequently a distinct gain in the concentration of effort displayed by M Vallot It is possible that the technique employed by him might be now improved, each succeeding Alpine investigator of a scientific character learns something from a predecessor, and this truth is plainly displayed in the account given by Zuntz already referred to, and in the more recent memoirs of Durig published this year in vol cxiii of the *Archiv f d ges Physiol* But the methods used by M Vallot appear to be fully adequate to determine the special points which he brings forward, and the results undoubtedly reveal certain features of the respiratory mechanism of no little special and general interest

It is common knowledge that the degree of the pulmonary ventilation is continually changing, this being due to alterations both in the frequency and the amplitude of the respirations, but if the amount of the air breathed in and out is estimated during the whole of a considerable period, these variations practically disappear It is thus possible to obtain a series of total volumes of pulmonary ventilation, each number in the series being that of some given period, such as an hour, or a day of twenty-four hours The work described by M Vallot consists in framing such series, both for himself and for M de Goumoens, when resident in Chamonix, during a prolonged stay in the Mont Blanc Observatory, and again on return to the Chamonix level His observations have thus been made continuously for considerable periods, and each period has comprised the ascent to the observatory, residence there, and the return to Chamonix On comparing the observations made respectively first at the low level then at the high altitude, and finally at the low level again, certain differences are brought to light

In the first place, M Vallot shows that his method is adequate to display the diurnal variations in the total pulmonary ventilation which occur at ordinary levels independently of the muscular exercise, and which are undoubtedly related to food assimilation With regular meals and sound digestion these variations occurred in the results obtained in Paris, and in Chamonix, their general character was a series of rises in the total amount of the hourly ventilation, each rise came on after a meal, and lasted for a given period before it declined towards its old level These diurnal food variations in the pulmonary ventilation persist, according to M Vallot's observations, when the subject is living at a high altitude, and their character is unaltered provided the regimen of diet remains the same and there is no obvious impairment of the digestive system

The most important part of the observations is, however, that which contains a series of the daily ventilation aggregates In regard to these, M Vallot considers them from two standpoints — (1) that in which the aggregate volumes of the respiratory tidal air are measured at the temperature and pressure which they have in the lungs this he terms the "real ventilation", and (2) that in which the same aggregate volumes are all reduced to what they would be at 0° C and 760 mm Hg pressure— this he terms the "absolute ventilation" The "real ventilation" he takes as an index of the amount of the total thoracic enlargement, and thus of the mechanical work of respiration, whilst the "absolute ventilation" he takes as an index of the quantity of air and of its oxygen component introduced into the lungs for the purposes of the organism His general results may be briefly set forth under these two aspects

(1) *Changes in "Real Ventilation"* —All observations of an extended character on real ventilation quantities show in each individual occasional variations occurring irregularly, and not accounted for either by muscular movements or, apparently, by food These irregularities became far more conspicuous during prolonged residence in the observatory, and indicate that the organism when in elevated regions, is in a condition of greater instability as regards its body processes, with due caution M Vallot declines to give any more definite hint as to their meaning If these irregularities are put on one side, the mean level of a whole series of daily aggregates is seen to be considerably affected by the high altitude of 4350 metres The effect is a rise, which in M Vallot (regarded as a trained subject) was immediate on arrival at the observatory, it amounted to a total daily increase in "real ventilation" of 30 per cent over the Chamonix figures It was very slightly increased during the stay in the observatory, and immediately fell on descending again to the lower level It was not the consequence of the muscular efforts involved in the ascent, and appears to have been a direct response of the organism to the lower atmospheric pressure there is thus an increase in the mechanical work of the thorax and lungs at high altitudes

In the case of M de Goumoens who is described as an "untrained subject" this immediate rise in

[1] "Annales de l'Observatoire météorologique, physique et glaciaire, du Mont Blanc." Tome vi Pp vii+218 Publiées sous la direction de J Vallot, Fondateur et Directeur de l'Observatoire (Paris G Steinheil, 1905.)

ing to 45 per cent over the Chamonix figures, it was increased during the prolonged stay at the observatory, and on descending to Chamonix it only partially fell to the level of the ventilation before the ascent, an excess remaining for many weeks

(2) *Changes in "Absolute Ventilation"*—The importance of this series of calculations rests on the possibility of comparing these changes with those in the "real ventilation," for it will be clear that if the views advanced by M Vallot are sound, then such comparisons will indicate how far the augmentation in the "real" values through extra thoracic enlargement has sufficed to compensate for the diminution in the actual quantity of oxygen as the result of the diminished air pressure In the case of M Vallot who by frequent visits and ascents was a "trained subject," it appeared that the high altitude always caused on arrival at the observatory an immediate fall in the total value of the absolute ventilation, this fall, although not large, was quite distinct, so that the increased thoracic work was apparently insufficient to compensate fully for the diminution in the quantity of inspired oxygen caused by the lowered atmospheric pressure This continued for some days of the residence in the observatory, and then gradually became almost inappreciable, the deficiency being decreased by 50 per cent, indicating the gradual development of an acclimatisation compensation As in the real ventilation, so here the descent to Chamonix was necessarily associated with an immediate and complete return to the normal condition

The case of M de Goumoens is still more interesting because more marked He is spoken of as the "untrained" subject, and in his case the "absolute" value of the daily ventilation immediately fell considerably more than in the case of M Vallot This considerable fall occurred in spite of the circumstance that the compensatory thoracic work had shown a very marked increase The continued life in the observatory was in M de Goumoens's case associated with a much more notable adjustment of the absolute ventilation value than M Vallot (the "trained" subject) showed, so that by the second week the deficit had diminished by 80 per cent The descent to Chamonix was associated with the disappearance of the deficiency, but since the "real" value remained persistently increased, this caused the "absolute" value to be so much that instead of a deficiency there was now an excess of 30 per cent over the previous Chamonix figures Hence it appears that the respiratory mechanism responds by a compensatory increase, as regards mechanical work when the subject is brought into a low atmospheric pressure, that this response is immediate but is at this high altitude insufficient, and that the degree of insufficiency is less in those who have frequently undergone the experience A further compensatory increase is then gradually brought into play which adds to the total and makes the whole compensation more nearly adequate, but this does not as the immediate one does, cease when the subject returns to lower levels It would thus seem probable although M. Vallot does not himself give any definite suggestions on this point, that the immediate adjustment is one involving the respiratory nerve centres, whilst the slow adjustment involves the actual framework of the thorax

The total change in respiratory ventilation value, whether "real" or "absolute" being itself brought about by either greater amplitude or greater frequency of respiration, it was necessary for M Vallot to ascertain the share taken by each of these factors The changes in frequency were often very pronounced, but their periodicity and general character were so irregular that no direct relation between the real ventilation values and the frequencies could be ascertained. On the other hand, the results as regards amplitude were far more definite, and it would appear that this is the chief factor in the production of the compensatory effect. The details of the observations given by M Vallot under this head need not be referred to, since their general character will be sufficiently indicated by the foregoing remarks As regards the whole investigation, it will be evident that since several such series of experiments were undertaken, the researches described in this volume of the *Annales* indicate an immense amount of laborious and prolonged work, and M Vallot is to be congratulated upon the solidity of the contribution which he has made to the physiology of respiration, and upon the pertinacity which he has displayed in his conduct of the whole inquiry; this pertinacity, combined with a rigorous limitation of the inquiry to one issue, has resulted in genuine achievement

Two other short memoirs are bound up with the volume The first of these deals with meteorological observations made on the Glacier de Tête-Rousse by M Mougin and M Bernard during the following periods August 1 to October 15 1901; June 1 to October 10, 1902, and July 1 to October 13, 1903 The occurrence of rain snow, dew, &c, is noted, and the daily temperatures, minimal and maximal, are tabulated A series of special experiments was made as to the temperature of internal parts of the glacier It appears from those that at a depth of 15 metres the temperature remained constantly at 0° C throughout all the months of the year.

The third memoir is one by M Henri Vallot In this the author gives some further particulars as to the method which he has employed for mapping out the details of the Mont Blanc summit with its extensive glacier fields

F G

SUCCESS OF ANTI-MALARIAL MEASURES

TWO reports recently issued prove in a striking manner that malaria may be stamped out by the application of scientific measures directed against the malaria-bearing mosquitoes The first report deals with Ismailia[1] Malaria was introduced into Ismailia in 1877 and since 1886 nearly all the inhabitants have suffered from the disease In 1901, on the initiative of Prince Auguste d'Arenberg, president of the Suez Canal Co, Prof Ronald Ross was consulted, and, acting on his advice, a series of measures instituted which has had the welcome result of completely freeing Ismailia from malaria These measures consisted in the destruction of mosquitoes principally by filling in and draining the pools and marsh land, or treating these with petroleum where the Anopheles breed, concreting water courses, &c, and instructing the inhabitants and protecting their household water supplies. This has been attained at an initial cost of 50,000 francs, and an annual outlay of 18,300 francs.

These measures were commenced in 1903, and from that time the ordinary mosquitoes disappeared from Ismailia, so that mosquito nets are no longer necessary Since the autumn of that year not a single Anopheles larva has been found in the protected zone, and no fresh cases of malaria have occurred The number of cases of malaria per annum in Ismailia has been as high as 2500, and in 1902, before the

1 "Suppression du Paludisme à Ismailia." (Compagnie Universelle du Canal maritime de Suez, Paris, 1906.)

anti-malarial campaign, there were 1550! The report is illustrated with interesting plans and diagrams

At Port Swettenham, Federated Malay States, anti-malarial measures were commenced in 1901 and 1902, and the latest report,[1] by Drs Travers and Watson, shows how great a measure of success has been attained Among the Government employees, for example, in 1901 236 sick certificates were issued and 1026 days of leave were granted on account of malaria. In 1905 the figures were respectively four and thirty Comment is needless

NOTES

At a special general meeting of the Royal Society of Edinburgh, held on December 21, the council presented a report on the new accommodation to be provided for the society in consequence of its proposed removal from the Royal Institution, under the provisions of the National Galleries (Scotland) Bill We learn from this report that in March last a memorial was presented to the Secretary for Scotland directing attention to the needs of the society, and asking for a free grant of 600*l* a year In a semi-official reply to this memorial the general secretary of the society was informed that a proposal was being entertained by the Government to devote the whole of the Royal Institution to the purposes of art, and that the Royal Society must contemplate the necessity for finding accommodation elsewhere As it appeared from correspondence and an interview with the Secretary for Scotland that the Government had definitely decided to allot the whole of the Royal Institution for the purposes of art, the council resolved with great reluctance, to accept the necessity for removal and to do its best to secure adequate reinstatement An accommodation committee was therefore appointed by the society to advise the Secretary for Scotland regarding sites and buildings suitable for new premises for the society, with the result that the committee unanimously recommended the building at present occupied by the Edinburgh Life Insurance Office, Nos 22 and 24 George Street At an interview on November 22 Mr Sinclair offered, subject to the consent of Parliament, to purchase and adapt the George Street building on certain conditions, and in addition to give a free grant for the scientific purposes of the society The conditions proposed were approved by the representatives of the society present as being, in the circumstances, an equitable settlement of the claims of the society In a letter received by the general secretary indicating the nature of the proposals which Mr Sinclair intended to make in committee on the Bill in question it was made clear that the society was to occupy the building on identical terms with those of the occupancy of the Royal Society at Burlington House In the speech of the Secretary for Scotland on December 13, during the debate in Committee of the House of Commons on the Galleries Bill, the final proposals regarding the accommodation and grant to the society, recorded in last week's NATURE (p 179) were described Briefly the arrangements are that a sum of 25,000*l* will be used for the purchase of a building, and 3000*l* to cover the expenses of fitting up, redecorating the new premises, and transferring the library and other effects of the society from the Royal Institution The Treasury will also give the society a grant of not more than 600*l* a year The council expresses the opinion that these proposals meet the claims of the Royal Society both in respect of an additional grant and of reinstatement in suitable new premises In conclusion, the council remarks in the report that the society owes a debt of gratitude to the Scottish Members of Parliament, to various members of the Royal Society of London and to the British Science Guild for their loyal support in a time of difficulty The report of the council was, on the motion of Sir William Turner, seconded by Prof. Bower, received, and unanimously approved by the society at the special meeting on December 21

The death is announced of Dr A W Panton, tutor and lecturer on mathematics at Trinity College Dublin Dr Panton made several useful contributions to mathematical science and was the author, in conjunction with his colleague, Prof W S Burnside of a standard work on "The Theory of Equations"

The *Petit Parisien* recently invited its readers to vote on the question of the relative preeminence of great Frenchmen of the nineteenth century The result is recorded in Monday's *Times* Fifteen million answers were received, and Pasteur's name headed the list with 1 338 425 votes, Victor Hugo in the second place being more than one hundred thousand votes behind him In addition to Pasteur the following is the order of the names of men of science who appear among the first twenty in the list — Prof Curie, Dr Roux, Parmentier, who introduced the potato into France, Ampère, Arago, and Chevreul, the chemist It is clear from the results of this *plébiscite* that the French people cherish the memories of the scientific investigators whose work has contributed, not only to national renown but also to the advancement of knowledge throughout the world

Reuter reports the following severe earthquake shocks during the past few days --*December 22 Kopal, Semirechensk* —An extremely violent earthquake shock lasting one and a half minutes was felt in this district at 11 20 p m *Rome* —The seismographic instruments at the observatories of Bologna and Florence recorded in the evening a violent earthquake estimated to have originated at a distance of 7000 kilometres *December 26, Santiago de Chile* —A strong shock of earthquake is reported from Arica Shocks were felt at Iquique and Pisagua

A Reuter message from Naples states that a portion of the crater of Vesuvius fell in on December 20, with the result that a shower of ash fell over Naples for twenty minutes so thickly as to obscure all view of the volcano Later in the day the ash ceased to fall at Naples, but continued in the direction of Portici and Pompeii

The St Petersburg correspondent of the *Globe* reports that an expedition for the exploration of the Arctic regions is being equipped under the leadership of Lieut -Colonel Sergeyeff The expedition will last for several years, and will start from Yeniseisk, and try to reach Bering Strait

In the September number of *Terrestrial Magnetism* Prof G B Rizzo states that on September 7 1905 some hours before the Calabrian earthquake of last year a land surveyor at Monteleone found the needle of his compass so much disturbed that he was compelled to discontinue work In Japan great earthquakes have been known for some time to be preceded by magnetic disturbances, but we are not aware that any of these have been so large as that recorded by Prof Rizzo

The annual conversazione of the Royal College of Science and Royal School of Mines Students' Union was held on December 19 at the College in Exhibition Road, South Kensington There were exhibits and demonstrations

in mining and metallurgy, mechanics, geology, botany and zoology, and the Solar Physics Observatory was thrown open for inspection Prof W Gowland gave an illustrated lecture on "Stonehenge," and two lantern lectures were given by Dr W J S Lockyer on "The Photography of Clouds and Lightning"

A TELEGRAPHIC message in the *Times* of December 17 announces that Prof Koch who has for some time been engaged in investigating the causes of sleeping sickness in German and British East Africa, has proved that atoxyl is an effectual remedy against the disease The treatment is reported to have been successful in all cases which have so far been dealt with and it now only remains to test the permanence of the cures effected If this news proves to be true, Prof Koch is to be congratulated on finding a cure for this deadly disease which has already spread over the Congo Free State, has depopulated some of the most fertile districts of Uganda and is threatening the Sudan on the north and Rhodesia on the south It is, however, probably somewhat premature to speak of cures in a chronic disease such as this, which may run without treatment for several years Nagana which is closely related to sleeping sickness is an acute disease in horses, killing them in three or four weeks By giving the animals arsenic however, they may be kept alive for a year or more If one must wait a year to test the permanence of a cure by arsenic in an acute disease such as nagana, how much longer must one wait in such a slow, chronic disease as sleeping sickness, which may have a natural duration of years instead of weeks? Prof Koch's preliminary report will be awaited with interest

THE annual meeting of the Association of Economic Biologists will be held at Cambridge on January 9, 10, and 11 The laboratories in the pathological department of the University and the zoological laboratory will be thrown open for the occasion On January 9 the president Mr F V Theobald, will deliver an address on sea fisheries The following papers will be read during the meeting —Red-water fever and allied diseases, Prof Nuttall, F R S , cereal breeding, H R Biffen , new hemipterous fruit pests in Britain F V Theobald, Intorno agli esperimenti contro la Mosca delle olive (*Dacus oleae* Rossi), Prof A Berlese, on the American gooseberry mildew, an epidemic fungus disease now invading Europe, E S Salmon, the successful extermination of the black currant gall-mite, W E Collinge, the geographical distribution, natural and artificial, of the principal rubber plants, W G Freeman, notes on insect pests in the British East African Protectorate, F V Theobald, the spruce gall and larch-blight diseases caused by "Chermes" and suggestions for their prevention, E R Burdon, a description of an infectious disease occurring in hares, T Strangeways, the blood changes in man caused by the presence of metazoan parasites, and their aid in diagnosis, E G Fearnsides, on the use of an economic museum in the teaching of geography, W G Freeman

A BILL has been deposited in Parliament to incorporate the Channel Tunnel Company, and to authorise the construction of works which shall form part of the scheme intended to connect England and France by means of a railway in tunnel under the English Channel It is estimated that the scheme will involve a total outlay of 16,000,000*l* Half that amount is to be raised in this country, and the remainder is promised in France as soon as the scheme shall have received Parliamentary sanction in England It is proposed to construct two parallel tunnels, the total length of which under the sea is to be twenty-four miles, and with the land approaches on either side thirty miles The tunnels, each 18 feet in internal diameter, are to be driven from Dover to Sangatte throughout the whole distance in the grey Rouen chalk Power for the electric motors which are to be employed in the tunnel traffic is to be obtained from large generating stations, which are likewise to supply the current required for lighting and the compressed air necessary for the purposes of ventilation

No 7 of vol xvi of the Proceedings of the Royal Physical Society of Edinburgh is devoted to the second part of Dr T Scott's catalogue of the crustaceans inhabiting the basin and estuary of the Forth, this portion dealing with the ostracods, copepods, and cirripedes

To the November number of the *American Naturalist* Prof H F Osborn contributes the first portion of an article on the causes of extinction of species in mammals more especially the larger kinds After referring to the views of Darwin, Wallace, and Lyell, the author discusses in turn the influence of changes in the shape of land-masses and their connections, of climatic changes, especially increasing cold and varying degrees of humidity, of changes in the flora of countries brought about by climatic alterations, and finally, the effects of insect-life The concluding portion of the paper must be awaited before a summary of the author's views can be given In another article Dr Raymond Pearl discusses variation in the number of seeds in the lotus, *Nelumbium luteum*, while in a third Messrs J A Cushman and W P Henderson give the results of a preliminary study of the finer structure of the "test" of the fresh water rhizopod Arcella

IN the November issue of the *Quarterly Journal of Microscopical Science* Dr Georgina Sweet continues her account of the anatomy of the marsupial mole (*Notoryctes typhlops*), dealing in this instance with the vestigial eye This organ, despite the fact that its owner spends much of its time on or near the surface of the ground, is much more completely atrophied than in the mole the optic nerve and lens being wanting, while the other structures connected with vision are degenerated in a greater or less degree The eye itself has sunk deep beneath the skin which passes over it unaltered except for the presence of sensory (? tactile) organs developed from the lachrymo-nasal glands and ducts This complete degeneration of the eye may be attributed to the irritating effects of the particles of heated sand amid which the creature dwells, the development of the glandular structures into sense-organs being in all probability a compensation for the loss of vision

AMONG other articles in the November issue of the *Quarterly Journal of Microscopical Science*, one, by Mr F A Potts, is devoted to the modification in the sexual characters of hermit-crabs induced by the parasitic cirripede Peltogaster Two articles, one by Mr E Potts, of Philadelphia, and the other by Mr E A Browne, of University College, London, treat specially of the medusæ of the American fresh-water polyp Microhydra with notes on the two other known forms of medusa-producing polyps In a fourth article Mr C Shearer describes the structure of the nephridea of the annelid Dinophilus, which proved to be closed internally by "flame-cells," or "solenocytes," similar to those of certain polychæte annelids, the lancelet, and one form of the Phoronis larva The two remaining articles deal respectively with the canker of apple trees and Dr R Goldschmidt's recent monograph on the lancelets of the genus Amphioxides

THE report of the Board of Health on Plague in New South Wales in 1905 includes reports on the fifth outbreak of plague at Sydney, by Dr Ashburton Thompson, on outbreaks of plague on the Clarence and Richmond Rivers, by Mr R. J Millard, on an outbreak of plague at Newcastle, by Mr R Dick and appendices on the kind of printed forms used in investigating plague and on the epidemiology of plague, the latter being an address by Dr Thompson Again clear evidence is brought forward of the correlation between rat plague and human plague in the four localities of the outbreaks, and Dr Thompson's address gives a valuable summary of the epidemiology of the disease The report is illustrated with five maps and a chart

THE last Bulletin of the Madras Museum, under the editorship of Mr E Thurston contains an interesting monograph on the Paraiyan or Pariahs of southern India The name of this caste seems to mean "drummers" and the Rev A C Clayton, the author of the monograph accepts the theory that they are a people who in former times were priests of the non-Aryan or Dravidian races and that the detestation shown by the Brahmans to them is based on religious rivalry rather than on their foul course of life—the eating of carrion and the like Mr Clayton gives an interesting account of their religious rites, social and domestic ceremonies These have clearly suffered much modification under the influence of their Hindu neighbours, and they now retain little that is really primitive Thus they seem to have discarded the totemistic exogamous system of groups and their religion has been largely influenced by Hinduism This contribution to the ethnology of southern India gives a useful account of an interesting and little-known people

PARTS i and ii of the fifth volume of *Biometrika* were issued together as a double number at the beginning of this month The volume opens with a full and interesting memoir of the late Prof Weldon joint founder and co-editor of the journal who died last spring at the early age of forty-six, many of our readers may be glad to note that this memoir is also obtainable separately from the Cambridge University Press The following article is by Prof Raymond Pearl, on the variation of *Chilomonas paramoecium* under favourable and unfavourable conditions, it is shown that the individuals under unfavourable conditions are smaller than the others and of somewhat different shape, and the relation of these facts to the theories of Driesch and others is discussed The promised issue of the memoir by the same writer, on which some controversy recently took place in our correspondence columns, has, however, apparently been deferred to the next part Dr F A Woods and Mr David Heron, in two independent articles, conclude that neither in man nor in the horse is there any significant inheritance of the sex-ratio, nor is there any evidence of Mendelian inheritance—important contributions to the literature of this subject Dr Macdonell contributes a second study of the English skull, based on crania discovered during excavations in Liverpool Street, and Prof Pearson discusses the relations between intelligence and various physical and mental characters all such relations appearing to be very light The concluding article gives an account of an important investigation, by Dr J W Jenkinson, on the relation between the first furrow, the sagittal plane, and the plane of symmetry in more than 800 frogs' eggs, the results of this investigation show that the conclusions of some previous writers, based on the examination of very inadequate numbers of eggs, have been stated much too confidently the variation exhibited being very large indeed The miscellanea as usual contain a number of shorter articles, chiefly on minor points of statistical theory We note that Dr Macdonell, Mr Elderton, and Prof Pearl are now associated with Prof Pearson in the editing of the journal, and it may be hoped that this assistance will lead to a more regular issue than in the past

IN the second number of the Botanical Journal of the Imperial Society of Naturalists in St Petersburg, Mr and Mrs B Fedtschenko present an article collating the species of Campanulaceæ from Russian Turkestan In the course of an article on the flora of a district in the Government of Riazan mention is made of the discovery of pollen and seed from pine trees in the peat that would indicate the previous extension of coniferous forests many miles further south A description of plants newly recorded from the Crimea is contributed by Mr. A Younghé

ON the subject of cotton cultivation in the Bombay Presidency Mr F Fletcher contributes an instructive article to the *Agricultural Journal of India* vol i part iv Premising that the better the quality the longer the cotton takes to mature five regions are distinguished according to the nature of the soil and the amount of rainfall Of these, the Surtee-Broach and Karnatak tracts are said to be capable of producing the best indigenous cottons while on a portion of the Sind tract that is irrigated excellent Egyptian cotton has recently been grown In the matter of new cottons a promising hybrid is announced from the Surat farm, and cautious but sanguine views are expressed with regard to tree cottons of which two are discussed as forms of *Gossypium peruvianum* and *G barbadense*

AN interesting account giving practical details of the construction of a tramway in connection with the extraction of timber from the forests of Goalpara in northern India, is furnished by Mr W F Perrée to the September and October numbers of the *Indian Forester* For working the forests in question situated north of the Brahmaputra towards the Bhutan border neither sufficient labour nor animals could be maintained, further no water was available in parts of the district, for these and other reasons an experimental tramway was laid down, and subsequently extended for a distance of nine miles from the Brahmaputra Short logs sleepers and water tanks are conveyed on single trucks while large logs are placed on movable frames mounted on the trucks as bogies The details of construction and cost provide useful items for reference

DR E HOWARD ADYE whose careful "Twentieth Century Atlas of Microscopical Petrography" has already been noticed in these pages, is now issuing in parts a work entitled "Studies in Micropetrography," accompanied by actual rock-sections as well as coloured illustrations A prospectus and sample plate can be obtained from the publisher Mr R Sutton, 43 The Exchange, Southwark S E The rock-sections are of the same beautiful character as those issued with the previous atlas, and the subscription price of 4*l* 4*s* for forty-eight of these and twelve parts of the work cannot be regarded as excessive The plates and detailed descriptions should enable the student to go a very long way in self-instruction while the series of preparations would be welcome in any laboratory With a view to systematic arrangement later, we could have wished that the descriptions had been printed on separate and unpaged sheets The interesting volcanic ash of Mont Pelée is included in the first part issued Surely however it would be possible for Dr Adye to quote published litera

ture concerning this material He states that he has found none at present

THE physical papers read at the seventy-eighth meeting of the German Association of Naturalists and Physicians are published in No 20 of the *Verhandlungen* of the German Physical Society, and also in Nos 21 and 22 of the *Physikalische Zeitschrift* A striking case of "chemiluminescence" is described by Prof E Wedekind, the interaction of chloropicrin with magnesium phenyl bromide in ethereal solution is accompanied by the production of a green flame beneath the ether, without the latter, however, being caused to kindle or explode In a dark room the luminescence appears very intense An interesting lecture on the so-called "liquid crystals" was delivered by Prof Lehmann at a general meeting of the association, its general scope was to illustrate how the development of such "crystals" appears to mimic the phenomena usually supposed to be characteristic of the simplest forms of living matter

A COPY of a paper entitled "Niederschlag, Abfluss und Verdunstung auf dem Landflächen der Erde," prepared by Dr Richard Fritzsche to attain his doctorate (Friedrichs Universitat Halle-Wittenberg), has been received The paper is an attempt to re calculate from recent data the total yearly rainfall over the earth's surface, and to indicate the transference of water between land and sea The flow of water through the world's rivers is of course, also considered in detail, and in this connection a very full list of authorities and references is given, adding greatly to the value of the thesis In most cases the figure used is compared with that given by Murray The unit adopted is the cubic kilometre per year The total rainfall over the whole world is given by Fritzsche as 465,300 cubic kilometres per year, which is equivalent to a uniform depth of 91 centimetres Brückner gave 94 centimetres. The rain falling on land is estimated by Fritzsche as 111,940 cubic kilometres per year, by Brückner at 122,540 cubic kilometres and by Murray at 122,318 cubic kilometres per year The amount given by Fritzsche is equivalent to a depth of 75 centimetres Considering only the land which is drained by rivers into the sea, it is calculated that only 30 per cent of the water returns to the sea in this way, the remaining 70 per cent being removed by evaporation The tables which accompany the paper are very full and interesting

SINCE the publication of the first edition of his "Sinnesorgane im Pflanzenreich zur Perzeption mechanischer Reize" (Leipzig Engelmann) in 1901, Prof G Haberlandt has continued his investigations of the sense organs, or organs of perception of plants, and he includes his new observations in the second edition of his work just published The original volume was reviewed in NATURE of April 10, 1902 (vol lxv p 529)

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN JANUARY, 1907 —

Jan 2 7h Neptune in opposition to the Sun
3-4 Epoch of January Meteors (Boötids, radiant 230° + 53°)
4 6h Venus at maximum brilliancy
7 9h 56m to 12h 56m Transit of Jupiter's Sat III (Ganymede)
9 17h 44m to 18h 20m Moon occults γ Libræ (mag 4 1)
10 17h 12m Moon in conjunction with Venus Venus 0° 17′ N
13 Total eclipse of Sun, invisible at Greenwich
14 13h. 13m to 16h 13m Transit of Jupiter's Sat III (Ganymede)
Jan 16 Venus. Illuminated portion of disc = 0 353.
17 11h 28m Minimum of Algol (β Persei).
20. 8h, 17m. Minimum of Algol (β Persei).
21 9h. 7m to 10h 12m. Moon occults ζ² Ceti (mag 4 3).
24 Neptune 1° N, of 36 Geminorum (mag 5 2).
26. 2h 4m Jupiter in conjunction with Moon. Jupiter 2° 37 N.
" 6h 40m, to 7h 45m. Moon occults ν Geminorum (mag 4 1)
28-29 Partial eclipse of Moon invisible at Greenwich

COMETS 1906h (METCALF) AND 1906d (FINLAY) —From observations made at Mount Hamilton and Rome, Herr M Ebell has calculated a set of elliptic elements for comet 1906h, after finding that the observed places could not be satisfied by a parabola The time of perihelion passage, according to these elements, was October 10.714 (Berlin) and the period of the comet is 7 588 years. The elements exhibit a similarity to those of comets Faye, Wolf, 1892 V, 1896 V, and 1900 III, but it is improbable that comet 1906h is identical with any of these, although it probably belongs to the same family An ephemeris extending to January 28 is also given by Herr Ebell, but, as the comet is so extremely faint, it is not worth while to reproduce it here.

On December 8 Prof Hartwig, at the Bamberg Observatory, examined the neighbourhood of the comet, and of the star B D −3° 696, with a 10-inch refractor for the nebulous objects seen at Bordeaux on November 22, but was unable to find them (*Astronomische Nachrichten*, No 4141)

An ephemeris extending to March 22 is given for comet 1906d in No 4140 of the *Astronomische Nachrichten* by M L Schulhof This object is now very faint, and is about 1½° south of Pollux

TWO STARS WITH A COMMON PROPER MOTION —In vol lx of the Monthly Notices of the Royal Astronomical Society Mr Bellamy announced that the two stars AG Berlin B 5072–5073 have a common proper motion and this was confirmed later by Prof Kreutz Additional confirmation now comes from Prof Millosevich, who has compared the available observations since the year 1881 with more recent ones, the last of which was made at Rome at the epoch 1906 39 and finds the proper motion on a great circle to be 1″ 385 in the direction 142° 7′ (*Astronomische Nachrichten* No 4132)

OBSERVATIONS OF VENUS —Continuing his articles on "Planets and Planetary Observation" in the *Observatory*, Mr Denning discusses the observation of Venus in No 377, and points out that the difficulties attending such observations have hitherto prevented any final determination of the planet's rotation period, or of the nature of her surface markings

He also states that the best times to observe the planet are during the evening apparitions in the early part of the year and the morning apparitions which occur in the latter half of each year when Venus is above the horizon for a long time after sunset or before sunrise The chief observations of reputed surface markings which have been made since the time of Galileo are discussed at some length in Mr. Denning's notes

A BRILLIANT METEOR —Mr H E Wood, of the Government Observatory, Johannesburg, records, in No 4141 of the *Astronomische Nachrichten*, the observation of a brilliant meteor on July 16 in various parts of South Africa. An observer at Mbabane in Swaziland, describes the object as a large white ball with a long trail of sparks, and states that it split into two masses each larger than the full moon, whilst a loud explosion accompanied its disappearance Attempts to locate the object, which apparently struck the earth near to Mbabane, have been unsuccessful Mr Wood himself saw a meteor, which he believes to have been the same object, at Johannesburg, two hundred miles away at 8h 45m. p m (standard time of 30° E), but he heard no detonation, although the object was very brilliant and left a trail of sparks As a similar body was observed in Germany on the same evening, Mr Wood suggests that possibly the earth encountered a stream of meteoric bodies on July 16, and that both the observed meteors were members of the same stream

RUBBER CULTIVATION IN THE EAST, AND THE CEYLON RUBBER EXHIBITION

AN exhibition of "rubber" has lately been held in the Royal Botanic Gardens at Peradeniya, in Ceylon, with the most unqualified success, and the time is opportune to see where we stand, and to sum up the work of the scientific institutions which have been engaged in starting this new, and now very prosperous, industry

Rather more than thirty years ago it began to be evident that there was a possibility that, as in the previous case of cinchona, the natural wild rubber supplies—which were then almost solely South American—would in time be exhausted, and an expedition was sent by the Indian Government, aided by the Royal Botanic Gardens at Kew, to the valley of the Amazon, where seeds and plants of the Para rubber—*Hevea brasiliensis*—and other rubber-yielding plants were obtained and safely conveyed to Kew From Kew they were sent to the East, and as it was fairly evident that at that time there was no place in India suitable for their growth, they were sent to the care of Dr Thwaites, in Ceylon, the then director of the botanic gardens in that colony A few were also sent to Singapore and elsewhere These plants arrived in Ceylon in 1876, and were planted chiefly in the low-lying garden of Henaratgoda, which was specially opened for their reception

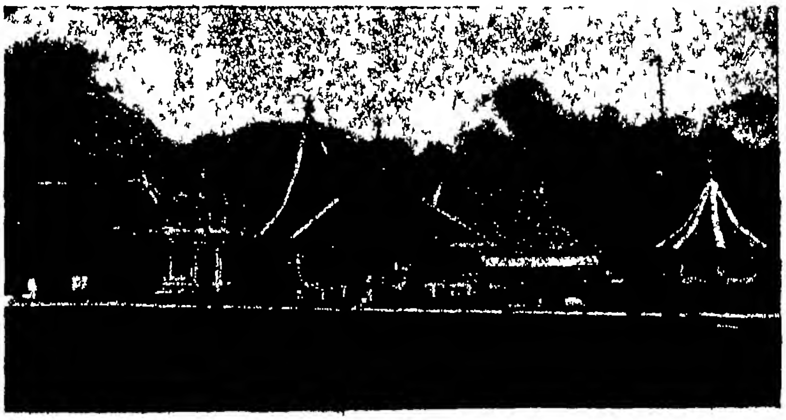
The trees began to seed about 1882 and from that time onwards practically all the seed has been used Of the earlier crops a large part was sent to other countries, but in later years most of the seed was used in the island In 1888 the late Dr Trimen, Thwaites's successor, began to tap one of the original trees at Henaratgoda, and in that year, working in the rough way then practised 1 lb 12 oz of dry rubber were obtained from it V-shaped cuts were made with a chisel, and the milky latex allowed to run down into cocoanut shells and to dry naturally The tree was given a rest in 1889, and in 1890 gave 2 lb 10 oz It was again tapped in every second year following and by 1896, in which year the experiment came to an end, it had yielded 13 lb 7 oz in the five tappings, and was twenty-two years old The average yield was thus about 1½ lb a year, but the tree was twelve years old when the experiments began and was also, instead of being of the average size, the largest tree in the plantation At this rate, therefore, there was but little prospect for success, especially with the price at the comparatively low figure which it then occupied

The next stage in the work was in 1897 when the writer found that the average yield of a plantation of trees about twelve years old might be about 120 lb an acre, and also made the very important discovery of the "wound response" It is found that the second tapping of a given area, provided it is made within about ten days, will yield a larger flow of latex than the first Thus, in the experiments just mentioned, the average yield per tree in the first week was 0 73 oz, in the second week 1 48 oz in the third 0 97 oz, fourth 0 80 oz, and only in the fifth did it fall below that obtained in the first week, being only 0 67 oz This is a discovery of very great importance and one of which a scientific explanation is very desirable From these figures it was calculated that a rubber plantation might show a profit of 27 per cent at the tenth year, and with this the taking up of the industry began in Ceylon, being handicapped only by the very limited supply of seed

In the following year Mr John Parkin came out to Peradeniya as assistant, and was at once started to work at rubber He worked out the whole question of the wound response, and, further, worked out in detail a new method of preparing rubber in far purer condition than had previously been the case Biffen had shown that the essential elements in the smoke used in South America were acetic acid and creosote, and Parkin applied this to the preparation of rubber in the East by collecting the latex in tins containing a little water (to prevent immediate coagulation) and mixing it with the calculated quantity of acetic acid and a little alcoholic solution of creosote The milk being filtered before treatment, the result was to clot it into a perfectly clean "biscuit," which, when rolled out and dried gave more than 93 per cent of caoutchouc, a much higher proportion than had ever before been found in any sample of crude rubber These biscuits were analysed by Messrs Michelin and Co, of Clermont-Ferrand, and after going through the washing machine emerged 99 per cent to 100 per cent against about 80 per cent for any of the best wild rubbers

This work caused a still further demand for rubber seed, but it was still only in limited supply, though the older trees upon private estates were now beginning to come into bearing, and by 1902 there was almost unlimited seed available. At the same time a demand was also springing up in the Malay Peninsula, stimulated by the action of the director of the botanic gardens at Singapore (Mr H N Ridley), who has steadily pushed rubber for many years

For the next three or four years planting went on slowly, and then about the latter half of 1902 began to be rapid, with the increasing supply of seed By the middle of the present year, 1906 there were in Ceylon alone more than 104,000 acres of land planted in rubber, almost solely the Para variety Of the other South American rubbers, the Ceara sort *Manihot Glaziovii*, was largely planted in Ceylon in the early 'eighties, but never quite realised expectations, and has never been more than a minor crop, though the export has never actually ceased The other, *Castilloa elastica*, is a very puzzling tree as yet It grows with great rapidity at first, and then slows down, and though it yields very freely at first tapping, it has no wound response and dies if too severely handled It has only, consequently, been planted on a very small scale as yet Para rubber on the other hand, seems to grow freely up to a small elevation in any part of "wet" Ceylon, and can be very roughly handled without, so far as can be seen, suffering any serious injury None of the other rubber yielding trees has given remunerative returns



Buildings of the Rubber Exhibition held at Peradeniya, Ceylon, on September 13-27

Not only are there already so many acres in Ceylon, but the Malay Peninsula has about 50,000 or 60 000 acres, and many other eastern countries have also considerable areas, all practically under Para rubber only, while in the west Mexico has, it is said, about 20 millions of trees of Castilloa planted, or, allowing 200 trees to the acre an area of about 100,000 acres This we believe to be an overestimate, but at any rate there is a very large area in that country Altogether it is probable that at the present time there are about 275,000 or more acres planted to rubber Allowing that the Para rubber yields twice as much as the Castilloa, this will represent about

230,000 acres, upon which, taking the present Ceylon figures, the eventual yield will be about 400,000 cwt., or 20,000 tons, about a quarter of the probable world's consumption at that date, and planting is going on at a very rapid rate.

The market for a short time looked askance at the biscuits, but they speedily came into favour, and have for a considerable time been receiving a higher price per lb. than the best wild rubber of the Amazon. But this must by no means be taken to mean, as it often is taken, that the plantation rubber is better than the "wild," for the latter contains about 20 per cent. of moisture, while the former is dry, so that in reality the wild rubber is getting about 16 per cent. more in price. Examination of the two qualities will at once show the reason for this difference; the plantation rubber is not quite so elastic, and when much stretched does not at once return, as does the wild rubber, to its exact pristine shape. What the reason for this difference may be is the great problem now before the scientific institutions working at the chemistry and botany of rubber in the tropics.

During the last four years the prices of rubber have continued to rise until they have now reached a height previously undreamt of. The result has been that the early pioneers of rubber cultivation have reaped enormous profits, amounting to as much, in some cases, as 60*l*. per acre per annum, and this has still further stimulated the rush into rubber planting.

The one topic of conversation in planting circles in the East is now rubber, and almost everyone, whether a planter or not, has invested in the industry, with the result that shares have risen very considerably, being in the case of companies owning bearing rubber now from three to eight times their par value. With this degree of interest excited in it it is hardly surprising that a proposal was made that Ceylon, the country in which most rubber was cultivated, should hold a rubber exhibition, and this was actually held in the famous Royal Botanic Gardens at Peradeniya from September 13 to 27.

Buildings upon a fairly extensive scale were erected in Kandyan or mountain Sinhalese style, and a large display of every kind of rubber was obtained, mainly, of course, from Ceylon and Malaya. There were also exhibits of tapping knives of every kind, and two large sheds were filled with the machinery that is rapidly coming into use upon rubber plantations. A very successful feature of the exhibition was the series of lectures upon every branch of rubber cultivation, shipment, and manufacture that was given during its progress, and which will shortly appear in a book which should be at the hand of everyone interested in rubber.

The bulk of the Ceylon exhibits were in the form of biscuits, the form originally adopted by Mr. Parkin in the laboratory having been long adhered to. The Malayan were in the form of sheets of larger size, but the most conspicuous things in the show, from this point of view, were some large blocks of rubber exhibited by the Linadron Estate in Jahore, made by pressing what is known as crepe rubber (obtained by aid of a washing machine) into solid blocks by powerful hydraulic pressure. Not only does this form offer less surface to oxidation, but it packs more closely, and thus saves freight, and it also sells for more upon the market.

The tapping knives for Para rubber exhibited much ingenuity, but not those for the other rubbers. It is worth pointing out here that persons interested—and who is not?—in introducing rubber cultivation into other countries should keep a sharp eye upon the development of the tapping knife in Ceylon and Malaya. Recent experiments in the West Indies, for instance, were carried out with a knife long since discarded in Ceylon, and the verdict was against this knife and in favour of the hammer and chisel, which form a very primitive tool indeed.

Some of the most interesting exhibits in the whole show were the samples of vulcanised and coloured rubbers, rubber and fibre mixtures, and other things shown by Mr. M. Kelway Bamber, Government chemist in Ceylon. These were referred to by Prof. Dunstan at the meeting of the British Association at York, and have aroused universal interest. Several technical papers have already given vent to the view that they can never be put to practical use, because each manufacturer has his own processes, which he will keep secret, for mixing and otherwise treating the rubber, apparently assuming that it is hopeless for the mere scientific man to find out such matters, or even to improve on them, or for one company, old or new, to take up the new process. Others, going on insufficient knowledge, have said that it is not possible to work with chloride of sulphur, or to mix other substances with the latex. In actual fact, the process is very simple, so simple that it seems a marvel that no one has found it out before. Instead of first drying the rubber into lumps or sheets, then macerating it, and mixing it with sulphur or other vulcanising material and colouring matters, these things are done *in the milk*, when the sulphur compounds will, of course, mix with the caoutchouc in a way that it is hopeless for any other method to equal, and when anything that can be wetted can also be easily incorporated, more especially colouring matters. In this way, by subsequent coagulation, a rubber is produced containing the vulcanising, colouring, and mixing reagents or substances in complete admixture. This can then be worked up in the ordinary way into any article that may be required, and finally heated, when it becomes vulcanised. Some of the most interesting exhibits shown by Mr. Bamber were the mixtures of rubber and fibre. The fibre is mixed with the milk in large quantity, the milk being previously sulphurised, and the mass is then dried, compressed under very great hydraulic pressure, and heated, resulting in a solid brick or tile containing but a very small proportion of rubber, and yet strong and elastic enough for the purposes of tiling or other uses.

This method of vulcanising will doubtless have to be modified in detail, but in principle is absolutely new, and is much simpler, and also much cheaper, than the present one.

Taking it altogether, the creation of the now great rubber industry, and its rapid progress from very rough and crude methods to a highly progressive and scientific spirit, is entirely the work of the botanical departments of Ceylon and Singapore, and they may justly pride themselves upon the result.

Recent Important Literature of Rubber.

"Para Rubber." By W. H. Johnson. (London.) Price 7*s*. 6*d*. A very good account of the industry as it was in Ceylon a few years ago, but already more or less out of date.

"Para Rubber." By Herbert Wright. Second edition. (Colombo: A. M. and J. Ferguson.) The best and most up-to-date account of the industry.

"The Book of the Rubber Exhibition of 1906." By J. C. Willis, M. K. Bamber, and E. B. Denham. (London: Dulau and Co.) Price 7*s*. 6*d*. To appear shortly. This book will contain the lectures given at the exhibition by numerous specialists, carefully revised and edited, many pictures, reports of judges, and other valuable features.

J. C. WILLIS.

METEOROLOGICAL NOTES.

"COLD Waves and Frosts in the United States" is the title of an important bulletin recently issued by the chief of the U.S. Weather Bureau. The work was prepared by Prof. E. B. Garriott; it includes a chronological account of historical cold periods in the United States since 1717, but deals more especially with the frosts that occurred from 1888 to 1902 inclusive, the conditions of which are illustrated by 328 charts. We have occasionally very cold spells in our own country, but these can scarcely be compared with those frequently experienced in the United States; as Prof. Moore has elsewhere pointed out, the area and intensity of cold waves depend upon the size of continents and their distance from the tropics. The author of the paper considers that the cold of the northern interior of the American continent is chiefly due to air that flows over that region from the northern Rocky Mountains, where its moisture has been precipitated, and to the process of radiation in its passage over Canada. The high barometer caused by the stagnant state of the air in this locality is one of the conditions that produce cold waves; another

necessary condition being the development of low barometric pressure near the southern margin of the cold-air belt, and the production of strong northerly currents due to cyclonic circulation. To quote only one instance of the value of forecasts in connection with these cold waves:—from January 6–12, 1886, a cold wave swept the country east of the Rocky Mountains and produced the lowest temperatures noted for the last fifty years in the south-eastern States. Speaking of this wave, Prof. Moore has stated that on January 7 there was a difference of 1·1 inch in barometric pressure between Montana and southern Texas, while the isotherm in Montana was −30° and on the Texas coast 50°. The people of the Gulf States knew nothing of the danger that threatened them until warned by the telegraphic weather forecast; on January 8 the temperature in parts of Texas had fallen to zero, and, notwithstanding the timely notice, the estimated damage to crops was 3,000,000 dollars in Florida alone.

Diurnal Range of Temperature in the Tropics.—Prof. J. Hann recently presented an important treatise on this subject to the Vienna Academy of Sciences. In continuation of a former work dealing with the district between lat. 15° N. and S., the one now in question relates to places in Africa and America (including the West Indies, Madagascar, and Mauritius) lying north and south of the above latitudes, and extending to the limits of the tropics and in some cases beyond them. The work is divided into two parts, containing, *inter alia*, (1) tables of the daily range of temperature in the form of departures of the hourly from the daily means, with a general discussion of the results, and (2) tables of the periodical and non-periodical amplitudes, and of the epochs of the daily maxima and minima, in connection with cloudiness, sunshine and rainfall. The mean occurrence of the minimum temperature at all places in the tropics (mountain stations excepted) is approximately at 5h. 30m. a.m., both on the coast and inland. The time of the maximum differs; on the coast and in rainy districts it mostly occurs soon after midday, at inland and dry stations it is at 2h. or even after 2h. 30m. p.m. At places on the West Indian coasts the maximum occurs about 42m. after noon, somewhat more inland, at Puerto Principe (Cuba) nearly an hour later, and at the City of Mexico about 2h. 48m. p.m. The occurrence of the daily mean is retarded according to distance from the equator; twenty-seven stations in the central zone (lat. 15° N. to 15° S.) give the mean time of 8h. 26m., twenty stations in the outer zones give 8h. 40m., as compared with 9h. 27m. at fifteen places in Austria.

Diurnal Variation of the Barometer.—In the *U.S. Monthly Weather Review* for April, Prof. Cleveland Abbe directs attention to an article in *Gaea* for August, 1905, by Dr. Korselt, of Annaberg, Germany, in which he attempts to show how the diurnal oscillation of the barometer is an important link in the chain of phenomena due to the unequal warming of the atmosphere by solar radiation and its unequal cooling by terrestrial radiation. One of his conclusions which may be recommended to the notice of meteorological organisations the telegraphic reporting stations of which generally possess self-recording barometers is that the minute study of the daily barometric oscillation may be of great value for practical weather forecasting, because it ought to give information about conditions in the atmosphere at altitudes which balloons have not yet been able to attain. A weather chart showing the observed difference between the barometric ranges by day and by night during the preceding twenty-four hours would, he thinks, probably show that any temporary area of low pressure has a tendency to move toward the region where the difference of the ranges is a minimum. Prof. Abbe points out, however, that these ranges are so small that they would often be completely masked by larger non-periodic changes, so that misleading errors would seem to be inevitable.

Influence of the Ocean upon Continental Precipitation.—In the same number Mr. F. O. Stetson (assistant editor) directs attention to a recent paper read before the Société helvétique des Sciences naturelles on the interchange of moisture between land and sea by Prof. E. Brückner. The author estimates that 93 per cent. of the water evaporated from the ocean is returned to it in the form of precipitation, leaving only 7 per cent. available for distribution over the land, and that of the total precipitation over the land 20 per cent. is supplied directly by the ocean, while the remainder is due to the re-condensation of vapour evaporated from the continents. We cannot give here the data upon which Prof. Brückner's figures are based, but if they are provisionally accepted as approximately correct, they indicate that the direct influence of the ocean upon rainfall over the land is less than has been generally supposed; but Mr. Stetson points out that the accurate determination of evaporation is a problem not yet solved, and that the rainfall over extensive tracts of land still remains unknown.

Wind Currents in the Vicinity of the Canary Islands.—In a recent note to the *Comptes rendus* of the Paris Academy, M. Teisserenc de Bort and Mr. Rotch have confirmed their opinion that the south-west winds observed on the Peak of Teneriffe correspond to a general phenomenon and are identical with those which would obtain over the open ocean, and consequently represent the regular anti-trade. This view is not in accordance with that held by Prof. Hergesell, to which he has again directed attention in *Beiträge zur Physik der freien Atmosphäre* (vol. ii., part ii.). He maintains that his observations with kites in 1904, and the balloon observations of the *Princess Alice* in 1905, show that in the latitude of the Canary Islands during summer north-west winds prevail to the greatest heights, and that there can be no question of a regular south-west current in that part of the Atlantic, the occasional south-west wind observed on the Peak of Teneriffe being due to local effects. Prof. Hergesell in no wise denies the existence of the regular south-west anti-trade wind, but maintains that at all seasons it is only to be met with some degrees south of the Canaries.

The Hong Kong Typhoon, September 18.—The Zi-ka-wei Observatory (near Shanghai) has sent us some interesting details relating to the progress of this most disastrous storm, which reached Hong Kong on September 18. The first signals of its approach were given by the Japanese observations in the islands east of Formosa on the morning of September 15, but owing to the distance of the stations from the central vortex it was not until the following day that it was clearly shown to be moving towards Formosa and China. The supplement to the Zi-ka-wei Daily Weather Report of September 30 contains some important extracts from ships' logs which clearly show the definitive track of the storm. The U.S. transport *Caesar*, bound from Cavite (Bay of Manila) to Shanghai, was at noon of September 15 in lat. 19° 53′, long. 120° 20′; at 4h. p.m. she had a steady wind from N.W., freshening in force to 7; the usual diurnal barometric range was still observed, but at 8h. p.m. the barometer, which stood at 29·60 inches, began to fall, the wind freshened and veered to N.N.W., and the ship was forced to steer S.W. to avoid the centre of the approaching storm. The observations were:—at 1h. a.m. on September 16, barometer 29·36 inches, wind N.W. 11; at 2h. a.m., 29·37 inches, W.N.W. 11; at 3h. a.m., 29·40 inches, W. 11; during this period the rain was continuous and excessively heavy. The centre of the storm passed between the ship and the south Cape of Formosa on September 16 shortly after 1h. a.m.

The P. and O. SS. *Delhi* was just entering the passes of Hong Kong when the typhoon burst upon the colony. At noon on September 17 she was in lat. 17° 58′, long. 111° 35′, about 420 miles from the vortex, wind S. force 2, and a distinct E.N.E. sea swell was noted. It was not until 4h. a.m. next day that the breeze veered to W. with occasional squalls, barometer 29·78 inches. The ship dropped anchor near Green Island, and the wind freshened, being W. by N., 8, at 9h. 30m. and W. by S., 10, at 10h. a.m., while the rain fell with blinding violence. At 9h. 45m. the barometer reached its lowest point, 29·14 inches. The centre of the storm passed to the north of the *Delhi* between 9h. 45m. and 10h. a.m. As shown by the observations of these two vessels and those of the French mail steamer *Océanien*, which left Hong Kong for Shanghai on the afternoon of September 17, the centre of the storm travelled from Formosa to Hong Kong, about 380 miles, in 56½ hours, at a mean rate of 6·7 miles an hour; the rate of translation was probably checked by the very high atmospheric pressure to the north, but it

became faster as the centre progressed nearer the coast, where it reached 143 miles an hour; the high pressure to the north also made the gradient steeper, and so increased the violence of the vortex. The track of the storm was approximately W.N.W. or W. by N.

The Rev. José Algué, S.J., director of the Manila Observatory, has published an article upon the above typhoon in the Monthly Bulletin of the Philippine Weather Bureau for September. The observations at Santo Domingo (Batanes Islands) and at Aparri (Luzon) show how accurate were the warnings and particulars of the track of the storm issued by the Zi-ka-wei Observatory, and that the typhoon passed close to the north of Santo Domingo between 3h. and 4h. p.m. on September 15, the centre moving in the direction of N.W. by W.; the barometric minimum at the latter place at 2h. 30m. p.m. on that day was 29.290 inches, the mercury having fallen 0.572 inch since 8h. p.m. on September 14. Father Algué thinks it probable that a depression felt at Guam (Marianne Islands), lying to the eastward of Santo Domingo, on September 8, may have been caused by the passage of the typhoon about 200 miles to the north of that station; in this case its mean rate of progression to Santo Domingo would have been about eight nautical miles an hour.

Report of the Fernley Observatory, Southport, for the Year 1905.—This institution, which is maintained by the Corporation, occupies an important position between the Liverpool Observatory and the anemograph station at Fleetwood, and possesses an exceptionally complete equipment of standard self-recording instruments. The year was very dry, the rainfall being 26.31 inches, or 7.11 inches below the average. Owing to the position of the observatory on the coast of the Irish Sea gales were experienced in every month, but although barometric pressure was lowest in November, this was one of the two calmest months, the other being May. The town enjoys a good amount of bright sunshine; in the year a duration of 1624 hours was recorded, or seventy hours above the average, being only about fifty hours less than at Brighton, and above 300 more than in the London district.

Annuaire météorologique, Observatoire Royal de Belgique 1906.—Although, as pointed out by M. Lancaster, an *Annuaire* is not indispensable for a meteorological organisation, the results of its observations being given in other publications, it is a very convenient method of bringing together data useful to different classes of workers, including agriculturists, engineers, medical men, and others. The work in question is certainly most valuable, and contains, in concise and handy form, the yearly and average results of observations made at Brussels (or Uccle) since 1833, together with a summary of miscellaneous information, including tables and constants which are both useful and instructive to meteorological students of any country. To render the publication more attractive, it contains from time to time original articles by members of the observatory staff. Amongst those contained in the current volume we may mention one by M. Vincent on weather prediction, illustrated by fourteen maps, as well worthy of attention. The author looks for future improvement in the wider dissemination of daily weather reports and the instruction of persons interested in drawing their own conclusions from the synoptic charts, in decentralisation to some extent, in the preparation of local forecasts as in the United States, and, eventually, in each person becoming his own forecaster, from information supplied by the central offices.

Climate of Alaska.—In the *U.S. Monthly Weather Review* for June reference is made to an important memoir on this subject by Dr. C. Abbe, jun., which forms part of Professional Paper No. 45 of the U.S. Geological Survey. Dr. Abbe summarises the materials collected during the last thirty years by the Signal Service and the Weather Bureau, and therefore supplements the useful memoir by Dr. Dall published in the Pacific Coast Pilot in 1879. The territory is divided into eight climatic provinces, for each of which much fresh information is afforded, especially as regards temperature and rainfall. The maximum shade temperature in the great Yukon basin is given as 90°, and 94° on the Copper River plateau, is the highest reported from any of the Weather Bureau stations, instead of 112° or even 120° formerly spoken of. The lowest recorded temperature is −80°, at Fort Reliance, in January. The largest annual rainfall is 170.09 inches, at Fort Constantine; the number of rain days is 251, at Unalaska, being the highest number at any point in the United States.

Meteorological Observations, Bremen, 1905.—The publication of the results obtained at this important observatory under the superintendence of Dr. P. Bergholz forms part of the German *Meteorologisches Jahrbuch*, which is prepared on a uniform plan for all parts of the empire. The present volume is of more than usual interest, as, in addition to hourly readings and means from self-recording instruments for the year in question, it contains monthly, seasonal, and yearly means for the lustrum 1901–5, results for the thirty-year period 1876–1905, and for all observations available from 1803–1905. As the latter are not quite continuous, we quote the following data for the thirty-year period:—mean temperature, January, 32°.5, July, 62°.6; the absolute extremes were 93°.9 (May 28, 1892), −13° (December 4, 1879); means of the absolute monthly extremes, 11°.1, January, 83°.5, July. The mean annual rainfall was 27.48 inches, July, 3.64 inches, April, 1.63 inches; the greatest fall in one day was 3.39 inches (June 10, 1884). The mean percentage of bright sunshine for fifteen years was 32.4, as compared with 29 per cent. in London for twenty years.

BRITISH INLAND WATERWAYS.

THE commissioners appointed early this year to investigate and report on this important question, have exercised a wise discretion in publishing, as soon as practicable, the first portion of the evidence given before them by fifty-four witnesses, at twenty-two meetings, held between March 21 and July 31, relating almost entirely to English canals and inland navigations. This first instalment forms a fairly bulky Blue-book, with 375 pages of evidence, an index of ninety-five pages, various appendices, together with a list of English inland waterways, occupying 111 pages, and a map of the canal-systems and navigable rivers of England and Wales in two sheets at the end of the volume, coloured so as to indicate each separate system, with the name of the system printed in large letters of the same colour.

Since the evidence here recorded was taken, the commissioners have been hearing evidence in Ireland on Irish inland waterways, and have also resumed lately their sittings in London; and they further propose to obtain detailed information with regard to inland navigation in the Continental countries of Europe where it has been most fully developed, which will doubtless be published in due course. Accordingly, considering the large amount of matter with respect to inland waterways which will be gradually collected by this commission, it is very advantageous that it should be given to the public at intervals to give an opportunity of its being properly studied; and this arrangement has the further merit that it will enable future witnesses, by seeing the previous evidence beforehand, to supply omissions or correct errors.

A perusal of the engineering evidence alone suffices to show by its conflicting nature, the magnitude of the task which lies before the commissioners, and the complicated problems which they will have to solve. The questions to be considered with regard to the improvement of inland waterways are:—first, the additional traffic that an improved waterway would be likely to attract; secondly, the size of barges which could most economically transport the traffic; thirdly, what would be the cost of a transformed waterway suitable for the passage of such barges, how far it should be carried inland, what connections should be formed with other waterways, and what return might be expected on the capital expended; and, lastly, by what means the funds might be raised for executing the proposed improvements.

The engineers of inland navigations being sometimes also the managers, or generally concerned in the management of their system, and being thoroughly conversant with the cost of improvements and with the working expenses, have for the most part dealt with the above questions in their evidence. One engineer suggests that the Government

should undertake the improvement of the tidal portions of the rivers; that above this limit the local authorities should improve the rivers by canalisation up to a town conveniently situated to form an inland port, up to which sea-going vessels of 400 or 500 tons could come, and which would serve as a distributing or receiving centre for waterways of suitable dimensions penetrating into the interior, and that in some cases, for surmounting high summit-levels, inclined planes worked by locomotives should be substituted for canals. Another engineer proposes that the Government should undertake through routes for vessels of 350 tons from Birmingham to Liverpool Hull, the Severn, and London, and between Liverpool and Hull, and from London to Bristol, and considers that these main routes would be certain to yield a profit on the purchase of the existing waterways involved in the schemes and on the expenses of construction, which could then be utilised in acquiring and improving other waterways A third engineer desires to make each river-basin a separate system; he considers that a barge of 150 tons is the largest barge that would pay, and instead of bringing sea-going vessels inland, he would bring these inland barges down to the tideway, where transhipment into sea-going craft would take place most conveniently A fourth engineer considers that 100-ton barges are the largest size expedient for English inland navigation, and that in certain cases the improvement of canals to accommodate them would not pay, whilst a fifth engineer thinks that any improvements of inland waterways would prove an unprofitable and useless expenditure

It is evident from this summary of the views expressed by some of the most experienced engineers with reference to inland navigation, that the commissioners, after having collected all the evidence available, will require some time to formulate their recommendations, and to decide how far Continental practice with regard to inland waterways is applicable to the special conditions of the United Kingdom

THE SCIENTIFIC STUDY OF INFECTIOUS DISEASES [1]

THE wider recognition of medical science as a rewarding object of endowment is a result of discoveries made during the last quarter of a century, and it is of interest to inquire why this increased knowledge should have borne such abundant fruit The result is not due to any change in the ultimate aims of medicine, which have always been what they are to-day and will remain—the prevention and the cure of disease—nor to the application to the solution of medical problems of any higher intellectual ability and skill than were possessed by physicians of past generations, nor to the growth of the scientific spirit, nor to the mere fact of a great scientific advance in medicine, for the most important contribution ever made to our understanding of the processes of disease was the discovery by Virchow in the middle of the last century of the principles and facts of cellular pathology, the foundation of modern pathology

The awakening of this wider public interest in scientific medicine is attributable mainly to the opening of new paths of investigation which have led to a deeper and more helpful insight into the nature and the modes of prevention of a group of diseases—the infectious diseases—which stand in a more definite and intimate relation to the social, moral, and physical well-being of mankind than any other class of diseases The problems of infection which have been solved and kindred ones which give promise of solution are among the most important relating to human society. The dangers arising from the spread of contagious and other infectious diseases threaten, not the individual only, but industrial life and the whole fabric of modern society. Not medicine only, but all the forces of society are needed to combat these dangers, and the agencies which furnish the knowledge and the weapons for this warfare are among the most powerful for the improvement of human society

[1] Abridged from an address delivered by Dr. W. H. Welch at the formal opening of the Laboratories of the Rockefeller Institute for Medical Research on May 11

Great as was the material, intellectual and social progress of the world during the past century, there is no advance which compares in its influence upon the happiness of mankind with the increased power to lessen physical suffering from disease and accident, and to control the spread of pestilential diseases

Before some accurate knowledge of the causation of infectious diseases was secured preventive medicine was a blundering science, not, however, without its one great victory of vaccination against small-pox, whereby one of the greatest scourges of mankind can be controlled and could be eradicated, if the measure were universally and efficiently applied The establishment upon a firm foundation of the germ doctrine of infectious diseases, the discovery of the parasitic organisms of many of these diseases, the determination by experiment of the mode of spread of certain others, and the experimental studies of infection and immunity have transformed the face of modern medicine

The recognition, the forecasting, the comprehension of the symptoms and lesions, the treatment of a large number of infectious diseases have all been illuminated and furthered, but the boon of supreme import to the human race has been the lesson that these diseases are preventable.

Typhus fever, once widespread, and of all diseases the most dependent upon filth and overcrowding, has fled to obscure, unsanitary corners of the world before the face of modern sanitation

In consequence of the knowledge gained by Robert Koch and his co-workers Asiatic cholera, to the modern world the great representative of a devastating epidemic, will never again pursue its periodical, pandemic journeys around the world, even should it make the start

Of bubonic plague, the most dreaded of all pestilences, which disappeared mysteriously from the civilised world more than two centuries ago, we know the germ and the manner of propagation, and, although it has ravaged India for the last ten years with appalling severity, it can be and has been, arrested in its spread when suitable measures of prevention are promptly applied

Typhoid fever, the most important index of the general sanitary conditions of towns and cities, has been made practically to disappear from a number of cities where it formerly prevailed That this disease is still so prevalent in many rural and urban districts of the United States is due to a disgraceful neglect of well-known measures of sanitation

To Major Walter Reed and his colleagues of the United States Army Commission an inestimable debt of gratitude is due for the discovery of the mode of conveyance of yellow fever by a species of mosquito On the basis of this knowledge the disease, which had been long such a menace to lives and commercial interests in the Southern States, has been eradicated from Cuba, and can be controlled elsewhere

Another army surgeon, Major Ross, acting upon the suggestion of Sir Patrick Manson, had previously demonstrated a similar mode of incubation and transportation of the parasite of malaria, discovered by Laveran, and it is now possible to attack intelligently and in many localities, with good promise of success, the serious problem of checking or even eradicating a disease which renders many parts of the world almost uninhabitable by the Caucasian race and, even where less severe, hinders, as does no other disease, intellectual and industrial activities of the inhabitants

The deepest impress which has been made upon the average death-rate of cities has been in the reduction of infant mortality through a better understanding of its causes The Rockefeller Institute, by the investigations which it has supported of the question of clean milk and of the causes of the summer diarrhœas of infants, has already made important contributions to this subject which have borne good fruit

No outcome of the modern science of bacteriology has made a more profound impression upon the medical profession and the public, or comes into closer relation to medical practice, than Behring's discovery of the treatment of diphtheria by antitoxic serum, whereby in the last twelve

years the mortality from this disease has been reduced to nearly one-fifth the former rate

The most stupendous task to which the medical profession has ever put its hands is the crusade against tuberculosis, the preeminence of which as the leading cause of death in all communities is already threatened. Sufficient knowledge of the causation and mode of spread of this disease has been gained within the last quarter of a century to bring within the possible bounds of realisation the hopes of even the most enthusiastic, but it will require a long time much patience, and a combination of all the forces of society, medical, legislative educational, philanthropic, sociological, to attain this goal

But great and rapid as the progress has been, it is small in comparison with what remains to be done. The new fields which have been opened have been explored only in relatively small part. There still remain important infectious diseases the secrets of which have not been unlocked. Even with some the causative agents of which are known, notably pneumonia and other acute respiratory affections and epidemic meningitis, very little has yet been achieved by way of prevention. The domain of artificial immunity and of the treatment of infections by specific sera and vaccines, so auspiciously opened by Pasteur and by Behring is still full of difficult problems the solution of which may be of immense service in the warfare against disease. Of the cause of cancer and other malignant tumours nothing is known although many workers with considerable resources at their disposal are engaged in its study. With the change in the incidence of disease due at least in large part to the repression of the infections of early life increased importance attaches to the study of the circulatory renal, and nervous diseases of later life of the underlying causes of which we are very imperfectly informed. There are and will arise medical problems enough of supreme importance to inspire workers for generations to come and to make demands upon all available resources

In full recognition of the dependence of success in the warfare with disease upon increase of knowledge the Rockefeller Institute for Medical Research was founded by the enlightened munificence of Mr John D Rockefeller, to whom grateful acknowledgment is made. Likewise to the broad sympathies and active interest of his son, Mr John D Rockefeller, jun the origin and development of this institute are largely indebted

May the hopes of the founder and of those who have planned this institute be abundantly fulfilled! May it contribute largely to the advancement of knowledge and may the streams of knowledge which flow from it be "for the healing of the nations"

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

A RECENT report of President Butler, of Columbia University refers to the salaries paid to the professors and adjunct professors of the University. This part of the report was reprinted in Science for November 23. President Butler says that these salaries are inadequate and that the effects of this inadequacy are deplorable. The report shows that the present average salary paid to a Columbia University professor is but one-half of the sum fixed as necessary thirty years ago and that the cost of living has meanwhile increased between 10 per cent and 20 per cent. The purchasing power of the average salary of 1900 is therefore, hardly more than 40 per cent of the purchasing power of the salary established in 1876. In other words the great expansion of the University, which has been brought about by the labours of the university teachers has also been brought about at their expense. In President Butler's judgment the most important need of Columbia University at the present time is an addition to the endowment fund sufficient to enable the establishment and maintenance of a proper standard of compensation to members of the teaching staff. There are 119 professors and thirty-nine adjunct professors, 158 in all. To increase the salary of each by only 200*l* on an average—not at all an adequate amount—would absorb the interest at 5 per cent on a capital sum of more than 600,000*l*. The need is so imperative and the public interests affected by it are so important, the report states, that the mere statement of it ought to bring the needed sum, great though it is, from the American men and women who are the large-minded possessors of wealth

THE scheme for the establishment at Bristol of a university for the west of England is now taking definite shape. The sum of 40,000*l* has already been promised, and with the buildings of University College, which are worth about another 50 000*l*, the scheme may be said to have made a good start. There was a difficulty in arriving at an arrangement between the Merchant Venturers' work in higher education and that of University College, but we understand that the Merchant Venturers have practically accepted the principle of the proposed university and though details remain to be settled, there is good reason to believe that the movement will now go forward with every promise of success. Speaking at the Merchant Venturers' Technical College, Bristol, on December 20 Prof M F Sadler referred to the energy with which the Merchant Venturers had furthered the work of technical instruction, and expressed the hope that it would be found possible to unite the Technical College with the University College, and thus to form the nucleus of a great University of Bristol. Under modern conditions universities should combine opportunities for advanced technological, commercial and professional training with the highest tradition of literary and philosophical culture. There is still room, in spite of other recent foundations, for a new university in England with its seat at Bristol, but the nation will not gain by the establishment of a university weak because ill-endowed and insufficiently equipped with teachers, laboratories, libraries, and the buildings indispensable to the social side of university life. The rapid growth of Bristol in recent years encourages the hope that its citizens will emulate the example of Manchester Liverpool Birmingham Leeds, and Sheffield in the building up of a great modern university

SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 8 — "On the Occurrence of Encystation in *Trypanosoma grayi*, Novy, with Remarks on the Method of Infection in Trypanosomes Generally" By Prof L A **Minchin** Communicated by Prof Ray Lankester

In a former communication to NATURE (November 15 p 56) an account was given of the results obtained by the Sleeping Sickness Commission at Entebbe Uganda, with regard to the transmission of the *Trypanosoma gambiense* of sleeping sickness, and other trypanosomes, by *Glossina palpalis*, the dusky tsetse-fly[1]. It was shown (1) that the infection was a "direct mechanical" transmission by the proboscis, and that no "cyclical" infection comparable to that of malaria, could be discovered, (2) that *T gambiense* appeared to die out in the intestine of the fly after ninety-six hours, (3) that besides *T gambiense*, the fly carried two other species of trypanosomes, named *T grayi* and *T tullochii* respectively

Since the article referred to was written, it has been found that *T grayi* becomes encysted in the hind-gut of the fly and all analogies with other Protozoa suggest that the cysts are destined to be cast out and infect fresh hosts probably in this case, the vertebrate hosts from which the fly obtains the trypanosomes. This suggests the occurrence of a hitherto unsuspected mode of infection by trypanosomes, in which the parasites, when taken up from the blood of the vertebrate by the blood sucking invertebrate, pass in the gut of the latter, through a developmental cycle, which ends in the parasites becoming encysted. In this condition they are cast out and re-infect the vertebrate host by contaminating its food or drink. Such a mode of infection is termed "contaminative," as contrasted with the "inoculative" method seen in malaria and hitherto vainly sought for in these trypanosomes

[1] Mr E E Austen, of the Natural History Museum, has suggested to the author that *Glossina palpalis* should be distinguished in this way from the other seven known species of tsetse flies

Moreover, as it may be supposed that what one species of trypanosome does another may do, the encystation seen in *T. grayi* arouses the suspicion that the disappearance of *T. gambiense* from the gut of the fly may be due also to a similar cause.

Society of Chemical Industry, December 3.—Dr. J. Lewkowitsch in the chair.—The direct estimation of antimony: H. W. **Rowell.** The sample of finely powdered ore or fine metallic sawings containing about 0·14 gram of antimony is weighed into a 500 c.c. beaker and dissolved in 25 c.c. of strong hydrochloric acid. 5 c.c. of saturated solution of bromine in hydrochloric acid are run in, and any insoluble matter is fused in caustic soda and returned to the main bulk. Three grams of sodium sulphite are added, and the mixture boiled down to 10 c.c. to drive off sulphurous acid and arsenic. The solution is titrated at a boiling temperature, after the addition of 60 c.c. of hydrochloric acid (1–3), with N/20 potassium bromate until the colour of the methyl orange indicator is destroyed. The bromate is standardised with 0·082 gram of arsenious oxide dissolved in hydrochloric acid, which is equivalent to 0·1 gram of antimony. Copper raises the result slightly, and iron very slightly, but precautions are given for obviating their effect. The method may be applied to materials containing antimony, and examples are given illustrating the accuracy of the method, the effect of copper and variations in samples of alloys.—The detannisation of solutions in the analysis of tanning materials: Dr. J. Gordon **Parker** and H. Garner **Bennett.** The authors deal with the four chief methods used for the analysis of tanning materials and extracts, and compare the official method of the International Association of Leather Trades Chemists, which consists of detannisation by means of a column of prepared hide-powder in a specially made filter bell, with the German method, with the method devised by Kopecky, and, finally, with the official American method. The authors confirm the work that has been done by Reed and other American chemists, and disprove the claims made by Paessler that a dry chromed hide powder used in the filter bell gives the most accurate results. The authors finally recommend that the International Association of Leather Trades Chemists should at once adopt the American method, either as it now officially stands or in a modified form.

Geological Society, December 5.—Sir Archibald Geikie, Sec.R.S., president, in the chair.—The geological conditions which have contributed to the success of the artesian boring for water at Lincoln: Prof. E. **Hull.** This boring has its source of supply in strata which rise to the west, but to the east dip down towards the North Sea. The water-yielding stratum is reddish, soft, porous sand-rock, reached at a depth of 1561 feet, and penetrated to a depth of 474 feet. About one million gallons of water rise to the surface daily. The sand-rock belongs to the New Red Sandstone. The hydraulic pressure at the bottom of the boring is that due to about 2035 feet, and the friction of the water in percolating the rock accounts for the fact that the water can be pumped down during the day but rises again in the night. The formations penetrated are:—Alluvium and Lower Lias, 641 feet; Rhætic beds, 52 feet; Red Marl and Lower Keuper Sandstone, 868 feet; Bunter Sandstone, 454 feet. The quantity of water drawn from the New Red Sandstone amounts to not less than twenty million gallons, and the total available quantity of water percolating into the Sandstone amounts to about 300 millions.—Notes on the raised beaches of Taltal (northern Chile): O. H. **Evans.** The town of Taltal is situated partly on the dry bed of a river and partly on an inclined plain that fringes the bays of the coastal ranges to the northward, and runs up the valleys. The material of this plain consists of sands and rounded gravel derived from the rocks of the adjacent hills, mingled with shells and some isolated boulders. The formation is impregnated with salt, and there protrude through it weathered remnants of former stacks and islets. The plain rises in terraces, the highest of which are somewhat obscure, and sometimes portions of these higher terraces are preserved in the stacks and islets. A second coastal shelf also occurs, marked by a line of shallow caverns. Beds of shells in the gravel, containing whale-bones, give evidence of the marine origin of the terraces.

Chemical Society, December 6.—Prof. R. Meldola, F.R.S., in the chair.—Action of reducing agents on 5-chloro-3-keto-1:1-dimethyl-Δ^4-tetrahydrobenzene: A. W. **Crossley** and Miss N. **Renouf.** Sodium in moist ethereal solution gives, as main product, 3-hydroxy-1:1-dimethylhexahydrobenzene, whereas sodium in absolute alcoholic solution yields a small amount of this alcohol, and to a much larger extent 3-hydroxy-5-ethoxy-1:1-dimethylhexahydrobenzene. With zinc filings in aqueous solution either in the cold or on heating, 3-keto-1:1-dimethyl-Δ^4-tetrahydrobenzene is formed, but zinc dust in either glacial or dilute acetic acid gives rise to 3-keto-1:1-dimethylhexahydrobenzene.—A new trinitroacetaminophenol and its use as a synthetical agent: R. **Meldola.** Mononitrodiacetylaminophenol when dissolved in a mixture of fuming nitric and strong sulphuric acids, yields 2:3:5-trinitro-*p*-acetaminophenol, which is remarkably active as a synthetical agent owing to the extreme mobility of one (position 3) of the nitro groups. By the action of various amines on the trinitro-compound substituted benziminazoles are produced.—Pinene nitrolamine: F. P. **Leach.** This nitrolamine and a number of its derivatives are described.—A *pseudo* semicarbazide from pinene: F. P. **Leach.**—Some derivatives of benzophenone. Synthesis of substances occurring in coto bark. Preliminary notice: W. H. **Perkin,** jun., and R. **Robinson.** 2:4:6:3′:4′-Pentamethoxybenzophenone, $(MeO)_2C_6H_3\cdot CO\cdot C_6H_2(OMe)_3$ (pentamethylmaclurin), is obtained when aluminium chloride reacts with a mixture of veratryl chloride and phloroglucinol trimethyl ether in presence of carbon disulphide. 3′:4′-Methylenedioxy-2:4:6-trimethoxybenzophenone,

$$CH_2:O_2:C_6H_3\cdot CO\cdot C_6H_2(OMe)_3$$

(oxyleucotin) was synthesised by treating a mixture of piperonyl chloride and phloroglucinol trimethyl ether in carbon disulphide solution with aluminium chloride. The syntheses of other related products by similar reactions are also described.—The liquid volume of a dissolved substance: J. S. **Lumsden.** Experimental results are recorded which prove that the following law holds, though certain irregularities due to the influence of the solvent exist. When a substance in the liquid state dissolves without change of volume, the same substance when in the state of solid or gas will, when dissolved in the same solvent, change to the volume which the same weight of it would have if it were a pure liquid at the temperature of solution.—A synthesis of terebic, terpenylic, and homoterpenylic acids: J. L. **Simonsen.** These three acids were synthesised from ethyl acetylsuccinate, ethyl β-acetylglutarate, and ethyl β-acetyladipate respectively by means of magnesium methyl iodide.—Influence of light on diazo-reactions, part i.: K. J. P. **Orton,** J. E. **Coates,** and (in part) F. **Burdett.** Solutions of diazonium salts in water, methyl or ethyl alcohol, acetic or formic acid, decompose rapidly on exposure to light, the product of the reaction depending on the solvent.—The viscosity of liquid mixtures: A. E. **Dunstan** and R. W. **Wilson.** Viscosity concentration curves of mixtures of water and sulphuric acid show a well defined maximum point corresponding with H_2SO_4,H_2O, and a minimum corresponding with $3H_2SO_4,2H_2O$.

Linnean Society, December 6.—Prof. A. W. Herdman, F.R.S., president, in the chair.—The physiology of the museum beetle, *Anthrenus muscorum* (Linn.) Fabr.: Prof. A. J. **Ewart.** The mischief wrought by this species in the National Herbarium at Melbourne is great, and is only kept in check by systematic use of a chamber impregnated by the vapour of carbon-bisulphide, in which the plants are placed for several days at a time. The use of corrosive sublimate is not advisable owing to the grave danger to health in a dust-forming atmosphere. The most remarkable feature of the larvæ is their power of feeding on dry material with less than 9 per cent. of water, and yet these larvæ exhibit the usual amount in their structure, averaging 70 per cent. The author suggests that the water may be

chemically derived from decomposition of the carbohydrate food they consume. Bacteria are present in abundance in the alimentary canal of these grubs, and oxidise the carbon of the food where no transpiration of water is possible.—Note on the origin of the name Chermes or Kermes: E. R. **Burdon**. The existence of the same generic name in two families of the Hemiptera is due to the following causes:—(1) that the dye-insect of the oak, *Quercus ilex*, Linn., had been known since the Arab conquest of Spain by the popular name of Kermes all over the south of Europe. (2) That Linnæus, apparently unaware of this fact, put the Kermes dye-insect into the genus Coccus, and employed Chermes as the generic name for another group of insects, amongst which he placed the spruce gall-insect. (3) That Geoffroy, objecting to this misapplication of a well-known popular name, used Chermes as the generic name for the dye-insect which Linnæus called Coccus. (4) That Boitard used the name for the same insects as Geoffroy, but spelt it Kermes. (5) That the majority of workers at the spruce gall-insects have retained the Linnæan name of Chermes, and at the same time Coccid authorities have naturally continued to use the name Kermes for the insect which had popularly been so-called from early times. The author concludes that, in view of the wide acceptance of both Chermes and Kermes, any alteration would only make confusion worse confounded.—Part x. of the reports on Biscayan plankton collected by H.M.S. *Research* in 1900: E. W. L. **Holt** and L. W. **Byrne**. An account was given of the fishes captured. It was remarkable that no fish-eggs or larvæ were taken in any of the thirty-seven hauls of the closing-net which explored the water between 2000 fathoms and fifty fathoms; they appeared to be confined to the upper 100 fathoms, and were rare at the surface. Nine species and six genera were recognisable, the deepest of which was *Gonostoma bathyphilum*, taken in the closing trawl between 2000 fathoms and 1500 fathoms. Several unknown larvæ are described and figured.

Royal Meteorological Society, December 19.—Mr. Richard Bentley, president, in the chair.—The Guildford storm of August 2, 1906: Admiral J. P. **Maclear**. This storm shows some very curious and interesting features in the remarkable violence of the wind, rain, and hail within a small area, and the suddenness with which it burst. There was an area of thunderstorms over the whole of the south of England on the evening of that day. The most violent storm, however, burst over Grayshott, on Hindhead, at 8.20, and pursued a narrow track through Godalming and Guildford to Ripley, five miles north-east of Guildford. The wind was of hurricane force, and blew down an immense number of trees and caused other damage, and also the loss of two lives. The rain, accompanied by large hailstones, was very heavy, as much as 1.17 inches falling at Grayshott in fifteen minutes. There was a magnificent display of lightning.—The metric system in meteorology: R. **Inwards**. The author did not discuss the general question of the advantages of the metric system over that in use by Britain and her colonies and the United States of America, but confined his remarks to the advisability of adopting some uniform system by all the meteorological observers upon the globe.

MANCHESTER.

Literary and Philosophical Society, November 27.—Prof. A. Schuster, F.R.S., in the chair.—Some points of chemical philosophy involved in the discovery of radium and the properties of its combinations: Dr. H. **Wilde**.—A collection of land and fresh-water Mollusca collected by Mr. S. A. Neave in North-East Rhodesia: J. Cosmo **Melvill** and R. **Standen**. The areas traversed by Mr. Neave were mainly the high plateaux and mountainous lands between the Loangwa and Kafue Rivers, at an elevation of 2000 feet to 4200 feet. Mollusca were, in certain places (particularly Kapopo, in the limestone district), plentiful in individuals, but deficient in number of species. Most notable were the large agate-snails (Burtoa, Achatina, and Limicolaria), of which one elegant form, *A. rhodesiaca*, remarkable for its attenuately-fusiform contour, is new to science. *Cleopatra mterizensis*, one of a fluviatile genus, endemic in the African continent, is also until now undescribed, as is an interesting member of the sinistral genus Lanistes, which occurred at Kapopo, and is to bear the name of *L. neavei*, after its discoverer. Only twenty-two species are gathered in all, the majority being already known as natives of German East Africa, the Nyassa district, the neighbourhood of Victoria Nyanza or the Zambezi River. Little specific affinity seems to exist with the Transvaal or South Africa, excepting so far as some widely distributed species, *e.g.* *Melania tuberculata*, Will., and *Physopsis africana*, Krauss, are concerned.

DIARY OF SOCIETIES.

SATURDAY, DECEMBER 29.

ROYAL INSTITUTION, at 3.—Signalling to a Distance: the Invention of the Electric Telegraph: W. Duddell.

PLANT DISPERSAL AND KINDRED PROBLEMS

Observations of a Naturalist in the Pacific between 1896 and 1899 By H B Guppy Vol ii Plant Dispersal Pp xxvi+627 (London Macmillan and Co, Ltd, 1906) Price 21s net

FEW of the problems that confront the naturalist are wider in their range of interest than those connected with the origin of the present inhabitants of an oceanic island Such a population is almost always a very mixed one, though it can usually be roughly divided into two classes, the one embracing the aboriginal or endemic element, whilst the other is composed of colonists hailing, it may be, from widely-sundered centres of emigration But closer investigation shows that such a distinction is, after all, not a very profound one The forbears of the endemic groups were themselves at one time colonists, time and circumstance have permitted and encouraged divergent variation, and so new types have arisen The *causes* responsible for the variation itself for the most part elude recognition and their study is the business of the physiologist rather than of the naturalist, but the *effects* may well serve to concentrate the attention of the latter on the larger problems bearing on the nature and significance of adaptation no less than on those more directly concerned with the sources and mode of dispersal of the individual species

Mr Guppy, in his "Observations of a Naturalist in the Pacific," has kept both sets of problems clearly before him, and has produced a book that will deservedly appeal to a wide circle of biologists, and indeed, to all who are interested, not merely in the details, but also in the philosophical aspects of distribution

The author will probably not expect his ideas to command universal assent It is inevitable and indeed desirable, that divergence of opinion should exist as to the true explanation of phenomena which are still but imperfectly comprehended But such dissentience in no way detracts from the value of his work Perhaps the highest praise that can be earned by any contribution to science is to say of it that its facts are really facts, and its theories whatever be their ultimate fate, are stimulants to further research

Although the book before us deals with matters affecting the distribution of plants in general, the subject is more especially considered in relation to the littoral floras of the Pacific islands The author takes as types to illustrate the wider bearings of his own observations the floras of Hawaii, Tahiti, and Fiji He discusses very fully the various causes which in the case of the three island groups chosen have produced results so dissimilar, notwithstanding the equality of conditions which at first sight appears to prevail between them

The keynote of the explanation advanced to account for the facts is to be found in the buoyancy of the seed or fruit But whilst many of the author's conclusions are both suggestive and interesting, it may be doubted whether others will be prepared to accept his views as to the connection between buoyancy and habitat

Put briefly, his position is this The capacity of floating determines the position of those species possessing buoyant fruits or seeds by the river or on the coast Which of the latter stations is actually occupied will depend on the degree of transpiratory activity on the part of the plant, that is to say, on whether it happens to be a xerophyte or not If the former, then it will be chiefly restricted to the coast, but if not it will be precluded from occupying a position that is only suited to plants that can withstand physiological drought, and it will be driven to take up its position by the river or pond Mr Guppy expressly and repeatedly states his conviction that it is not the station which is responsible for the development of buoyant seeds, but that the plants so characterised reach and colonise littoral or riparian stations because they can be distributed to them, in other words, position does not determine buoyancy, but buoyancy determines the station subject to the further sorting out process which is associated with xerophilous or hygrophilous habit

But the author himself shows that seeds or fruits of the same species may exhibit great variation in their power of floatation some sinking at once when placed in sea water, whilst others from the same tree may float without injury for months He goes farther than this, and emphasises the need in making such tests, of taking seeds from plants grown under similar conditions Thus in *Ifelia bijuga* experiment showed that of the seeds taken from a littoral example 70 per cent floated in sea water whilst of those gathered from an inland individual of the same species only 25 per cent were able to swim Several other similar examples could be cited Such evidence would seem, however, to indicate that the environment is not without its direct influence in determining the floatability or the reverse of the seeds, and clearly if this is so natural selection has material enough to work on At any rate one would hesitate before accepting the author's conclusions as to the real relation between buoyancy and station

A very useful account is given of the several structural features to which buoyancy may be due As they are often remarkably simple it seems not unreasonable to think that an experimental study of the direct reaction of the plant to the environment in such cases as these would almost certainly yield interesting and valuable results

The author has some excellent remarks on the nature and origin of adaptive characters and they deserve to be carefully read by members of that large but somewhat careless class of naturalists who imagine that when a structure has been shown to be useful for a particular purpose its occurrence is thereby "explained" Nothing can be farther from the truth, and the more we know of "adaptive" structures the less directly does their origin appear to be related with the function they ultimately dis-

charge One might go so far as to suggest that it is only by accident that a character developed at one period in the life-history becomes of use at another, for such utility almost always involves a change of primitive function that could not have been foreseen at the first appearance of the structure in question Thus to quote the case of the floating mechanism, the stimulus that provokes the formation of air-filled spaces is most often connected with respiration, and they are first "adapted" for this purpose Their subsequent use for floatation is an accident It is true it may be of immense importance to the *species*, but its value could not, so to say, have been foreseen by the individual in which it arises

A chapter on mangroves forms an interesting diversion from the main track of the thesis It is known that curious barren forms of the genus Rhizophora occur in various regions These apparently combine the characters of more than one species, but the suggestion is put forward that they are not hybrids, but represent examples of dimorphism The hypothesis is rather startling, but it is very well worth while testing If it should prove to be well-founded, the investigation would certainly yield results of considerable scientific importance

Limitations of space preclude the possibility of attempting to discuss the great bulk of new and interesting observations that crowd the pages of Mr. Guppy's book, but enough has been said to show that the author has made a very real contribution to biological science J B F

PETROLEUM AND ITS PRODUCTS

Petroleum and its Products By Sir Boverton Redwood Two vols Pp xxxii + 1064 Second edition, thoroughly revised and enlarged (London Charles Griffin and Co, Ltd) Price 45s net

NO harder task exists than to criticise a book with which the reviewer is in complete accord, and so perfect an example of what a book of reference should be as Sir Boverton Redwood's monograph on petroleum and its products, of which the second edition has now been issued, offers no mark for criticism

The ten years which have elapsed since the first edition of this work was published have seen many advances in the industrial use of petroleum products, and a period which has been marked by the growth of the use of liquid fuel from the experimental stage to the important position it now occupies in the principal navies of the world, and the perfection of the internal combustion engine with its widespread application, has brought in its wake so many alterations and modifications in processes that a complete revision, and indeed re-writing, of a very large portion of the book has been necessitated, the two volumes now containing more than a thousand pages.

The first section of the work deals with the history of the petroleum industry, from the use of bitumen in building the Tower of Babel down to statistics as recent as 1904, and this portion of the work is rendered the more valuable by the data being subdivided under the headings of the various countries in which petroleum is found.

The geological and geographical distribution of petroleum and natural gas occupies the second section, which is illustrated by maps of the principal oil-bearing districts, and cross sections of some of the more important oil fields and wells. A consideration of the oil fields of the world naturally leads to the discussion of the chemical and physical properties of petroleum and natural gas, which occupies the third section of the work, and contains a wonderfully complete compilation of the enormous amount of work which has been done on the subject, and which is rendered the more valuable by the references being given for all the works quoted

The next section deals with the much-vexed question of the origin of petroleum and natural gas, and a discussion of the various theories which have been from time to time formulated, and although the balance of evidence is distinctly in favour of the views expressed by Hofer and Engler, as to petroleum being of animal origin, whilst natural gas is a secondary product of the same decomposition, the reader cannot help the conviction that there are many cases in which a vegetable or even inorganic origin might have caused the deposits

The fifth section will be considered by many readers one of the most important in the work, dealing as it does with the methods adopted for winning the crude oil, and much of the practical information as to the methods employed in the American, Canadian, Russian, and other oil fields is founded on the author's own experience

The important subject of refining the oil, which occupies the next section, covers not only the general methods employed, but also the details of the methods of manufacture adopted in America, Russia, and elsewhere, and is enriched by numerous references and extracts from the work of Engler and other Continental authorities too little known in England

The shale oil industry, being of British origin, claims a large amount of interest, and the struggles of James Young in founding it on its present basis form a fitting introduction to the seventh section, dealing with shale oil and allied industries, whilst an able section on the transport, storage, and distribution of petroleum ends the first volume of the book

To the chemist the second volume is even more interesting than the first, as the reader is at once plunged into the methods adopted for the testing of crude petroleum and the many products obtained from it, and especially interesting is the historical account of the early legislation with regard to the flash point, and the part played by Sir Frederick Abel and the author in fixing the flash point at its present value This section also contains a full account of the beautiful method of testing for petrol vapour and other inflammable vapours in air devised by Prof Clowes and the author, which depends on the fact that a hydrogen flame of fixed dimensions burning in air containing a small proportion of inflammable gas or vapour is seen to be surmounted by a small cap or halo, the size of which indicates the amount of in-

flammable vapour present in the air long before the mixture becomes itself inflammable

In these days, when petroleum spirit is so largely stored and used for motor purposes, and when so many steamers are engaged in the oil trade, tests capable of revealing any dangerous leakage of vapour are of the greatest importance, and the "flame cap" offers a certain method of detection

The tenth section of the work deals with the uses of petroleum and its products, and commences with a full description of the various types of oil lamp fitted for the consumption of mineral oils, and a full discussion of the dangers due to them A careful study of this portion of the section would do much to disabuse the minds of that portion of the British public which has been lately clamouring for an increase in the flash point, with the idea that this would minimise the danger of the oil lamp, and especially may the following paragraph be recommended to its notice —

"Experiments have demonstrated that the burning of an oil of comparatively high flashing point is more likely to cause heating of the lamp than the use of an oil of comparatively low flashing point, in consequence of the higher temperature developed by the former and of the greater difficulty with which some oils of that description are conveyed to the flame by the wick It therefore follows that safety in the use of mineral oil lamps is not to be secured simply by the employment of oils of comparatively high flashing point (or low volatility), and that the use of such oils may even in certain cases give rise to dangers, which are small, if not entirely absent, with oils of comparatively low flashing point"

The use of oil in spray lamps, the so called "air gas," the enrichment of coal gas by carburetting carburetted water gas, oil gas, and natural gas are here all described and discussed, whilst the use of liquid fuel leads to a full description of the various methods which have been employed, but unfortunately the author's position as leading adviser on petroleum to the Admiralty has prevented his giving any extended notice of the advances which have made the liquid fuel installations of the British Navy the finest and most successful in the world The section closes with a short account of the principles upon which petroleum engines are constructed, but, as the author points out, the motor-car industry and consequent development of petrol engines has assumed such vast proportions that it now possesses a voluminous literature of its own, which has far exceeded the scope of the present work

A section on the statutory, municipal, and other regulations affecting petroleum and its products brings the work to a close, whilst a voluminous appendix and excellent index add to its value So full are the references to all original memoirs noticed in the book that a bibliography of the subject at first seemed hardly necessary, but Messrs W H and L V Dalton have compiled one which will rejoice the heart of every student of the subject

The petroleum industry is indeed fortunate in possessing such a work of reference, and Sir Boverton Redwood has done the world a great service in providing it

RECENT ADVANCES IN PHYSIOLOGY

Mercers' Company Lectures on Recent Advances in the Physiology of Digestion By Prof Ernest H Starling, F R S Pp x+156 (London Archibald Constable and Co, Ltd, 1906) Price 6s net

As time advances it becomes ever clearer to many of those whose business it is to consider the manner in which university teaching should be carried on that the usual systematic course of lectures on the whole range of any of the larger divisions of human knowledge is an anachronism surviving from the time when there were no good text-books, and knowledge had to be conveyed directly from lecturer to student

In all the medical schools of the country at the present day, professors or lecturers hold appointments which entail upon them the duties of lecturing over the whole of such subjects as systematic medicine, systematic surgery, physiology, or pathology and bacteriology It is to be hoped that within the progress of a single generation such appointments may have ceased to exist, and that the student of the future may be able to give to the laboratory or the clinique that large section of his time which is at present misspent in the lecture-room What applies to the long lecture course, too often extending over two whole winter sessions applies with equal or greater force to the text-book written upon the whole range of a large subject

The present volume forms a delightful and refreshing contrast to any such wearisome compilation, it consists of a short course of ten lectures given by a master worker to his students, chiefly upon the work done in his own laboratory by himself and his colleagues This appears to the writer to be the ideal of what a lecture course should be, namely, something stimulating to enthusiasm and capable of sending the listener into the laboratory with the desire to work and learn more - a contrast in every sense to the mechanical lecture which must wade monotonously through everything, and, gramophone like, repeat from year to year the phrases and the stereotyped long-dead thoughts of text-books devised on the same mechanical system It is to be hoped that such special courses of lectures and specially written text-books, given and written by those in living touch with the subject in hand, may soon replace the universal lecturer and universal text-book

Naturally, in order to present in intelligible form the work of any one laboratory, it is necessary to place it in its appropriate setting to the work of others which has preceded it and led up to it, and to give for completeness contemporary work being done elsewhere, but such an account will be given by one who has gained a complete mastery of it at first hand for the purposes of his work, and will always be real, live, and interesting as compared with the account of one who has read it only to compile a text book or give a course of lectures

These ten lectures on recent advances in the physiology of digestion are an example of this and are full of interest from start to finish, by which is not meant that one follows the author in a quiescent state of en-

joyment and contented agreement from lecture to lecture, for, otherwise, one is more inclined to be continually stopping and arguing by the way, but at the same time it is felt that one is being thoroughly instructed upon the present state of knowledge of the subject by a master worker who has himself been engaged upon the problems involved.

The book is a record of a course of lectures given in recognition of a generous gift by the Mercers' Company in aid of the work of the physiological department at University College, London; a similar course is to be delivered each year, and it is to be hoped they will also be published.

This first course treats of the foodstuffs and their changes during digestion, the mode of action of ferments, secretion of saliva, digestion in the stomach, pancreatic secretion, changes in the pancreas during secretion, the properties of the pancreatic juice, the bile, the intestinal juice, and the movements of the alimentary tract. It is the "growing border," as the author himself styles it, of these important subjects which is mainly treated of, and to take up and criticise all the new work and theories involved would occupy more space than the little volume itself.

There is, however, one view of general interest with regard to the action of ferments or catalysts which here, as elsewhere, scarcely receives the consideration it deserves, and appears to be accepted without criticism. This is the law of Ostwald, that in order that an intermediate compound may be regarded as a sufficient explanation of a catalytic process, it must be first demonstrated that the rapidity of formation of the intermediate compound, and the rapidity of its decomposition into the end-products, are *in sum* greater than the velocity of the reaction without the formation of the intermediate body.

The error in this statement is the implied supposition that these three velocities are constants, in which case the law would follow—but a reaction is not constant throughout its range, beginning with high velocity and decreasing as the equilibrium point is approached. Further, for the reaction to run, all that is necessary is a potential quantity of the intermediate body, which would tend to be formed with very high velocity, so that the necessary and sufficient condition is that the intermediate body should decompose to form the end-products with greater velocity than does the initial substance when present alone. The greater velocity is obtained because the intermediate body formed with the catalyst gives a path of less resistance, so that the same chemical potential difference leads to equilibrium in a shorter time.

BENJAMIN MOORE.

SCIENCE AND ROAD-METAL.

Attrition Tests of Road-making Stones. By E. J. Lovegrove. With Petrological Descriptions by Dr. John S. Flett and J. Allen Howe. Pp. xx+80. (London: The St. Bride's Press, Ltd., n.d.) Price 5s.

MR. LOVEGROVE'S attrition-tests have been carried out systematically for some years past in the modest but unique museum of the Hornsey Town Council, an institution devoted to the useful arts of building-construction, sanitation, and public works in general. Here the compact machine figured on p. vii makes itself heard from time to time, when the stones undergoing the tests are lifted by the internal flanges of the three revolving cylinders, and fall a distance of eleven inches in their cast-iron prisons with painful iteration. After 8000 revolutions, what is left of them is taken out, and the chips and dust broken from them are separately estimated. The production of chips, as Mr. Lovegrove points out (p. vi), is an indication of brittleness, but may not be injurious to a road. The dust, which is determined in a dry experiment and also by one in water, is so much pure waste when formed on a road-surface or in the layer of macadam itself. The melancholy and pebble-like appearance of certain stones after they have suffered from Mr. Lovegrove's inquisition can be well seen in the Hornsey Museum, or in Figs. 77 and 78 of the present volume.

The director of the Geological Survey of Great Britain has encouraged this excellent series of experiments by forming a collection of tested stones in the Museum of Practical Geology in Jermyn Street, while Dr. Flett and Mr. Howe have supplied Mr. Lovegrove's volume with petrological descriptions and photographs from microscopic sections. Indeed, these valuable additions form the greater part of the book, though the eye is unpleasantly attracted from them to the large-type advertisements which are distributed throughout its pages. Mr. Howe's "general conclusions" will be read with special interest, and we cannot help quoting the following from them:—(P. 67) "The hardest and toughest stones combine *abundance of a hard mineral—e.g. quartz—with a dense fine-grained texture.*" (P. 69) "The very best rocks in these tests are altered rocks, and as a general rule a certain amount of alteration of the felspars seems to be an advantage. The reason for this is that the alteration produces a *number* of mineral units where formerly only *one* existed; in other words, the texture is made finer, and often the interlocking of the grains is made more complete." (P. 70) "*Fineness of grain* makes for toughness in all classes of stone."

The alteration of basic felspars of course often results in the crystallisation of granular minerals of hardness superior to that of the original material. Mr. Howe notes, moreover (p. 60), that uralitised augite is an advantage in dolerites, while augite altered to chlorite and calcite is naturally defective. Microscopic examination probably assists more in the case of rocks of the diorite, dolerite, and diabase type than in any other series, and this alone makes the practical field of the petrologist a wide one. The engineer and the experienced user of roads will, of course, recognise other grounds for the selection of this or that stone than the results of the attrition-test alone. Flints, for instance, which stand out well in the tests, are unsuited for countries with dry summers. Well-rolled limestone, on the other hand, where dry days are liable to follow dewy nights, as in the Apennines, may provide an admirable and cement-

like surface For ordinary moist climates, however, these tests serve as a clear condemnation of all limestones Even the gritty Kentish Rag (p 45) comes out badly, though, in combination with the ferruginous sandstones of our Lower Greensand, it has been known to make a road that held well together in dry seasons

The question of composite roads would be an interesting study in itself Materials showing great differences under the attrition-test should, of course, not be used in association, but roads made of mixed gravel taken out of streams show good results in many parts of Europe Similar material is usefully supplied by the glacial gravels nearer home Teachers of practical geology, as well as all county and borough surveyors, will be grateful to the three authors for providing a remarkably cheap, clear and thoughtful treatise on a subject that the whirligig of time has again made of national importance G A J C

DYNAMO DESIGN

Elementary Principles of Continuous Current Dynamo Design By H M Hobart Pp x+220 (London Whittaker and Co) Price 7s 6d net

IT is scarcely necessary at this date to recommend a book by Mr Hobart on the design of direct current dynamo machines, it is safe to say that any production by this author will repay the study of practical men, and the present book forms no exception

The contrast presented between a volume setting forth the results of the practical experience of a man engaged in actual work and a book evolved out of the inner consciousness of a man who has access only to the theory of the subject is very striking Books of the former class are comparatively rare, and are correspondingly valuable

Dealing in a general way with Mr Hobart's work the first point that strikes one favourably is the emphasis laid on the necessity of a large amount of application on the part of the student of the principles and methods set forth These principles and methods must be regarded as the framework on which a designer is to build, and it is folly for him to assume that he is acquainted with the subject unless and until he has gone a long way in completing the structure by his own labour The value of the book lies in the essential soundness of this framework more particularly of the fundamental ideas on which it is itself based than on the framework itself The commercial point of view is not instinctive with designers, and it is of the greatest importance that it should be acquired as soon as possible For this reason Mr Hobart has done well to lay stress on the necessity of judging every design by taking into account its first cost as well as its technical merits

Regarded in this way, the book consists of a series of statements explaining the way in which a dynamo should be considered as a successful machine or the reverse, and of a short account of several methods whereby the designer may himself estimate the first cost

After preliminary chapters on what may be called the practical theory of the continuous current dynamo, Mr Hobart deals at length with those considerations which form the limits in the design, namely, heating, sparking, and efficiency Numerous constants and formulæ are given, and miscellaneous information from which efficiencies can be calculated The sparking data are, naturally, based on the method of reactance voltage, introduced some years ago by the author and Mr Parshall, although a long list of references is given to those who have contributed to the theory in recent years This method, or some modification thereof, is so widely used that there is no necessity to describe it here The constants for dealing with the heating and the efficiency are, perhaps, the least praiseworthy part of the book, or rather not so much the constants as the general method The treatment in both cases seems somewhat arbitrary, for instance it is not absolutely certain that the rise in temperature of the armature is proportional to the total watts lost—copper plus iron loss—divided by the area of the cylindrical surface Again, the method of estimating the iron loss in the armature is distinctly rough This point has been debated at considerable length in the columns of the technical Press, but in the present writer's opinion there are other methods which certainly give better results The calculation of the bearing friction and windage is referred to a single curve giving the relation between this loss and the value of D^2L at the speed of 1000 revolutions per minute, but there seems to be no indication as to how the loss varies with the speed whether in direct proportion or as the 1 5th power of the speed

These slight discrepancies somewhat diminish the value of the book as a work of reference, but the essential feature of the book consists, as already stated, in the enforcement of a general grasp of the whole problem, commercial as well as technical

The book contains a large number of tables in which the various calculations are set out, some are filled in and others are left blank for the convenience of the student It will thus be seen that this is a work which can be thoroughly recommended to the student and the designing engineer alike

OUR BOOK SHELF

Irrigation with Surface and Subterranean Water and Land Drainage By W Gibbons Cox Pp viii+297 illustrated (Sydney Angus and Robertson, 1906)

THE author of this book has been engaged for many years in Australia in water supply and irrigation works There are vast areas of land in that country the soil of which is of the highest fertility but is barren and comparatively useless because of periodical aridity The problem of irrigation of the land from the rivers and creeks that flow at times through these districts, and form inexhaustible accumulations of underground water, is treated fully and practically according to the latest and most approved methods

With all its natural wealth and resources Australia is subject to the great drawback of occasional droughts of greater or less severity The consequences of one of these droughts is thus graphically described —"The natural water supply of the dis-

trict had become exhausted by use and evaporation, and the livestock were dying, while the women and children were beseeching the conductor of the Government water train—sent for the use of the line repairers' camp—to give them water Along the dried-up beds of creeks and lagoons, miles of bleached bones of dead cattle and sheep lay exposed to view The poor brutes, in their intense suffering, had ventured for a drink of the last water left, and sinking down, weak and helpless, had perished in the vain attempt to quench their dying thirst Overhead a scorching sun was shining like molten brass, and the heat waves of the atmosphere rendered the eyesight powerless to define objects at a distance, all vegetation lay withered The birds dropped gasping from the trees The experience of that drought was sufficient to impress any man, engineer or other, with the need of finding a remedy "

The process of sinking artesian wells for irrigation is fully and practically described, from those of shallow depth that can be sunk by hand labour, to the more extensive and deeper sinkings that penetrate to a depth of 6000 feet, and require the use of a 50 h p engine, and cables for raising and lowering the drills which weigh 6½ tons, the cost running up to 8000*l* The question of irrigation and the distribution of water, treatment of alkaline water, and drainage are dealt with in separate chapters In the appendix the statistics are given of the public artesian borings with their depths and yield It shows that these range from 46 feet in depth and a yield of 9000 gallons a day to 4086 feet and a yield of 1,000,000 gallons a day, the highest temperature of the water flowing out being 135° F

This book should be of great service to colonists settled in arid districts

Through the Telescope By James Baikie Pp xv+292 (London A and C Black) Price 5s net

THIS handsomely illustrated volume bears the impress of having been written by a practical observer who has suffered all the little worries and difficulties inevitably encountered by the amateur astronomer in his days of inexperience and meagre instrumental equipment Whilst treating of the sun, moon, planets, &c, in special chapters Mr Baikie writes of things he has observed and of difficulties he has overcome

The two opening chapters deal with the telescope, first from the historical, secondly from the practical standpoint The latter may be heartily recommended to beginners, who by carefully digesting and mentally assimilating it may save themselves much worry and, mayhap, expense We question, however, whether some of the advice is not a little too detailed, some things are better left to actual experience, others to common sense, *e g* the instruction on p 44 for the observer to wrap up well and keep his feet warm

The phenomena of the celestial bodies are described in plain language, interspersed with practical hints as to observing them, which cannot fail to help the beginner in "star-gazing," and, if he follows the author's advice, in the specialised study of some particular class of objects

The historical narrative in each case is lucid and instructive, although there are notable omissions of important work The two appendices containing the designations and brief descriptions of "lunar formations" and "double stars, clusters and nebulæ which may be fairly well seen with instruments up to 3 inches in aperture" form a valuable addition to this volume W E R

The British Journal Photographic Almanac and Photographer's Daily Companion, 1907 Edited by George E Brown. (London Henry Greenwood and Co, n d)

THIS annual is so well known to our photographic readers, that in dealing with the present issue we can say that the volume, as in former years, maintains its high position as a mine of photographic information In fact, its presence in every studio becomes year by year more necessary, for as a book of reference on almost every photographic manipulation it is most valuable

In the present issue one of the features which has attracted our special attention is the excellent editorial article bringing together brief summaries of the various three-colour photographic printing processes To-day the subject of printing in colours is so absorbing the time of many ardent workers that such a survey of the various processes in use is very opportune Another section which will be read with much profit is the epitome of progress Here we have brought to our notice a classified summary of the advances made in the numerous branches of photography during the past twelve months The matter is arranged under various subheads, such as "Apparatus and Equipment" "Photographing Various Subjects," "Negative Processes," "Printing Processes," and "Colour Photography," so that for purposes of reference any particular subject can be easily found As in former years, the formulæ for the principal photographic processes and of the principal plate and paper makers, useful miscellaneous information, and numerous tables complete the volume Very complete indices add greatly to the utility of the work

British Flowering Plants By W F Kirby Pp viii+215 (London S Appleton, 1906) Price 5s net

THERE are many pleasing features in this small book that treats of flowering plants in a popular way The illustrations, if a trifle over-coloured, are characteristic, and the author describes the plants in a sufficiently technical manner to permit of their identification, on the other hand, the book hardly gives an adequate idea of the importance of the different orders, and so many foreign plants are selected for illustration that the most popular method of determination is not provided for commoner British plants

The title furnishes no indication of the most useful information in the book afforded by the numerous notes which the author has added from his own special branch of natural history, relating to the insects that frequent plants either for destruction or indirectly for construction This information is of value alike to the botanist and the entomologist, and the observer who proceeds to verify the references to plant-visiting insects is likely to obtain a deeper insight into the structure and ways of flowers than is necessary for mere identification The introduction is not a botanical success and requires careful revision

The Fauna of British India, including Ceylon and Burma Coleoptera Vol 1 (Cerambycidæ) By C J Gahan Pp xviii+329 (London Taylor and Francis, 1906)

THE series to which this volume is the latest addition is being published with the authority of the Secretary of State for India in Council under the editorship of Lieut-Colonel C T Bingham The present book is only the first part of the contemplated volume; another part, which will give an account of the Lamiidæ, is to be published later Other volumes on Indian Coleoptera will follow in due course

Radium and its Disintegration Products

IN NATURE of December 6, 1906, Mr. H. S. Allen has suggested that the difficulty encountered in introducing actinium with its four α-ray products between uranium and radium can be removed by assuming that the α particle is one-half of the helium atom, and he has applied this suggestion in a table showing six α-ray changes between uranium and radium. There would appear to be two serious and insurmountable objections to this view, however, viz. (1) the continuation of the same line of reasoning would lead to the assumption of no less than seven α-ray changes between radium and its final disintegration product, lead, while but four are known, and (2) the activity of the actinium in equilibrium with radium in minerals is entirely too low to permit any such conclusion.

That lead is the final disintegration product of uranium is, I believe, conclusively shown by the fact that in unaltered *primary* minerals from the same locality the amount of lead is proportional to the amount of uranium in the mineral, and that in unaltered primary minerals from different localities the amount of lead relative to uranium is greatest in the minerals from the locality which, on the basis of geological data, is the oldest.

In the case of a non-emanating, radio-active mineral containing no thorium, in which there is reason for assuming that the elements of the uranium-radium series have reached a state of equilibrium, the activity of the mineral in extremely thin films measured in an electroscope with a large ionisation chamber is about 5·3 times as great as the activity of the uranium present in the mineral. The activity of the radium itself is about 0·52 of the activity of the uranium, and the activity of the radium products of rapid change together about 2·4 times that of the uranium. The activity of the radium F (polonium) is probably about 0·55 uranium, and is certainly not less than 0·5. The combined activity of the uranium, the radium and the radium products is therefore about 4·5 times the activity of the uranium alone. This leaves an activity of only 0·8 that of the uranium which can be attributed to the activity of the four α-ray products of actinium. It was the knowledge of the approximate value of this factor which led Prof. Rutherford and the writer to conclude (*Amer. Jour. Sci.*, xx., 56, 1905) that actinium was not a direct product of uranium in the same sense as is radium.

The ranges of the four α particles expelled by the actinium products have been determined by Hahn, and the average range of the four is 5·6 cm. The range of the α particle from radium itself is 3·5 cm. according to Bragg and Kleeman. If the particles are similar we would expect that the average particle from the actinium products would produce about 1·6 times the ionisation of the particle from radium. Since the activity of radium itself is 0·52 times that of the uranium in the mineral, the activity of the four actinium products might be expected to be 0·52×1·6×4=3·32 uranium. The number actually found, as has been stated above, is only 0·8 uranium, or one fourth of this number.

It will be noted in the above that the activity of the uranium is about twice that of the radium present, which is in good agreement with the conclusion of Moore and Schlundt that there are two α-ray changes in uranium if it is assumed that the average range of the two uranium particles is about 3·5 cm.

Although speculations of this sort are of doubtful value, the following suggestion may be sufficiently interesting to warrant its intrusion:—if the two changes in uranium and the five changes in radium are each assumed to take place with the expulsion of *four* α particles and the four changes in actinium with the expulsion of only *one* α particle each, the conditions required by the relative activities of the various substances would appear to be fulfilled, and if, moreover, the mass of each α particle be taken as 1, then the indicated atomic weights of the successive elements are in fairly good agreement with the accepted values. We have then uranium=238·5, actinium=230·5, radium=226·5, and radium F (lead)=206·5. In making this suggestion I fully appreciate that I am taking liberties with the accepted value of e/m for the α particle.

It is of further interest to note that the activity of pure radium, calculated from the relative activity of the uranium and radium in minerals and the relative quantities present (Rutherford and Boltwood, *Amer. Jour. Sci.*, xxii., 1), is indicated as about $1\cdot4\times10^6$ times that of uranium, and the activity of pure radium bromide containing the equilibrium amounts of emanation and products of rapid change as about 3×10^6 times uranium.

BERTRAM B. BOLTWOOD.

Sloane Laboratory of Yale College, New Haven, Conn., December 17, 1906.

The α Rays

THE α rays from radium appear to start life without electric charge, and subsequently become charged owing to collisions with the gas molecules they strike in their path. It seems, therefore, worth while inquiring what their behaviour would be if they were liable to become discharged again at a later collision and to go on repeating this cycle during the ionising portion of their path. Very possibly the α particle is capable of losing more than one electron, in which case it would seem certain that it will have a greater charge at some portions of its path than at others. Looked at in this way the problem is a statistical one of considerable complexity, but my point of view will be sufficiently well illustrated by considering the average α particle to behave as if it had the following constitution. For a distance x of its path it possesses an electric charge e. This is succeeded by a distance x' during which its electric charge is e'. This is followed by a distance x with charge e, then a distance x' with charge e', and so on, repeating indefinitely. Let the particle have a mass m and initial velocity v_0, then confining our attention to a portion of the path so small that v_0 is not appreciably diminished by the collisions which occur, it is easy to show that the quantity measured by the electrostatic deflection as mv_0^2/e would really be $\frac{mv_0^2(x+x')}{ex+e'x'}$, whilst the quantity measured by the electromagnetic deflection as mv_0/e would be $\frac{mv_0(x+x')}{ex+e'x'}$. Thus the measurements would give v_0 correctly, but the quantity denoted by e/m would be $\frac{ex+e'x'}{m(x+x')}$. It is evident that the apparent value of e/m would be independent of the pressure at which the measurements were made, since change of pressure changes both x and x' in the same ratio.

It is interesting to see what would happen if the α particle were *uncharged* during one series of portions of its path, and carried the ordinary electrolytic unit of charge e during the alternating portions. If the alternate stretches were equal, this is what would be obtained if it were an even chance whether the α particle escaped with or without a charge after each encounter. In this case we should have $x=x'$ and $e'=0$, and the measured e/m would really be $e/2m$. On this view Rutherford's measurements would indicate that the α particles are hydrogen atoms with the normal charge instead of helium atoms with twice that charge.

It may well be that it is a matter of chance whether the atom struck or the α particle retains the positive charge after an ionising encounter, but I do not wish to imply that this warrants the conclusion that the α particle is a hydrogen atom. If we accept this conclusion we find ourselves face to face with serious difficulty in finding a place for helium in the story of radio-active change, but even if the α particle turns out to be a helium atom it is possible that its charge might vary periodically in something like the manner indicated. In this case the average charge would have to be twice the electrolytic unit.

This kind of view has the advantage of affording a

reasonable explanation of why the α particle ceases to produce ionising and other effects at a stage when it possesses a much greater amount of energy than that which is known to be required by a positive ion to produce other ions by collision These effects would cease when the uncharged particle was no longer able to become ionised by colliding with a neutral atom The energy (about 10^{-8} ergs) which it then possessed would represent the minimum energy which an uncharged particle must possess in order to shake out an electron on collision with a neutral atom

Even if these speculations are ultimately disproved by the facts, it is interesting to note that, with such a constitution for the α ray, the experiments would measure the velocity correctly whereas the mass, and therefore the kinetic energy, would be erroneous to the extent indicated

The Effect of Radium on the Strength of Threads

WE have carried out some experiments with cotton threads in continuation of those described by Miss Martin and one of us in NATURE of August 17, 1905 The following is a summary of the results obtained —

No difference in the effect was found when the emanation was continuously removed during the exposure by a current of air The same negative result followed an experiment in which it was sought to remove oxygen and moisture from the neighbourhood of the threads by enclosing radium and threads along with phosphoric anhydride in a tube from which the air was exhausted, some metallic sodium being afterwards heated to fusion in a side tube

When threads or a piece of filter paper, after exposure to radium are dyed with methylene blue, the exposed part is found to take a deeper colour than the rest This is given as a test for the presence of oxycellulose

A series of three-day exposures was made at increasing distances from the radium The effect was found to become inappreciable at 18 mm distance When the weakening produced was plotted against distance, the curve showed a corner at 9 mm, suggesting the similar feature found by Prof Bragg and others on the ionisation curves of α rays to mark the end of the effective range of one set of rays

A comparison under the microscope of the broken ends of exposed and unexposed threads showed that the fibres in the former case were straight up to their ends, while the unexposed fibres were curled back on themselves This would indicate a loss of elastic quality through the action of the

T[illegible] the Sea Coast by Earthquakes

[illegible] long discussed by geologists concerning the u[illegible] the land by earthquakes has been impressively [illegible] by recent events In the San Francisco *Argonaut* of November 3 1906, Prof H D Curtis, of the D O Mills Expedition of the Lick Observatory at Santiago Chile reports that the harbour at Valparaiso is now 10 feet shallower than before the earthquake of August 16 1906, and he concludes that the movement was mainly vertical In the Bulletin of the Geological Society of America for May 1906, Messrs Tarr and Martin give a memoir on the changes of level at Yakutat Bay, Alaska, produced by the great earthquake of September 3–20, 1899, two of the most terrible shocks of which occurred on September 10 and 15 The investigators prove conclusively that an uplift occurred extending along the whole Yakutat coast for more than a hundred miles, the maximum movement in Disenchantment Bay being 47 feet 4 inches Uplifts of 7 feet to 20 feet were common, while slight subsidences also occurred in a few places

In view of these facts how can anyone claim that the earth is entirely solid and deny the vertical movement of the land under earthquake forces as is done by Prof Suess in his great work on "The Face of the Earth"?

T J J SEE

U S Naval Observatory Mare Island, California, December 8, 1906

THE observations of Messrs Tarr and Martin in Yakutat Bay undoubtedly form a valuable addition to the knowledge we possess respecting sudden adjustments in the earth's crust

In September, 1899, a portion of the west coast of Alaska was shattered Fault lines were created or extended, and the displacements along these lines have been measured On January 31, 1906, off the coast of Columbia, and on April 18 of the same year in Central California, rock movements similar to those at Yakutat were recorded Every world-shaking earthquake—and there are about sixty of these per year—is an announcement of a molar movement We do not know the magnitude of the masses involved, but from measurements like those made by Messrs Tarr and Martin we may estimate them as being represented by one or two million cubic miles of rocky material

J M

Emerald Green Sky Colour

THE account of the colour of the sky on December 10, 1906, sent by your correspondent from St Moritz closely resembles an experience of a friend and myself on December 27

We were returning from a geological ramble to the west of Crediton, in Devonshire, and were walking eastward, while behind us and gradually overtaking us there had been for several hours a thick snowstorm which later on was to envelop us Between three and four o'clock in the afternoon we remarked the peculiar appearance of the sky, in your correspondent's phrase there was "instead of the usual blue a fairly large expanse of vivid emerald green" I may add that the ground was everywhere white from previous snow

It will be seen that the conditions in Devonshire on December 27 correspond as regards time of day, point of compass, and state of atmosphere with those observed at St Moritz on December 10

With J W Noble I shall await with much interest the explanation F G COLLINS

Perception of Relief by Monocular Vision

THE following fact seems to show that the aperture of the pupil plays an important part in the perception of relief by monocular vision

When a polyhedron made of wire is looked at through a small pin-hole pierced on a piece of card and the pin hole is moved about slightly the polyhedron seems to rotate a little about an axis perpendicular to the direction of motion of the pin hole The effect is most remarkable by lamplight, when the pupil is more dilated than it is in broad daylight T TERADA

THE GEOLOGY OF THE GERMAN ANTARCTIC EXPEDITION[1]

THE most striking geographical achievement of the German Antarctic Expedition was its determination that Antarctica occurs farther north in western Wilkes Land than had been inferred by some authorities from the work of the *Challenger* Prof von Drygalski and his comrades have re-established faith in Wilkes's Termination Land, as from their Kaiser Wilhelm Land they saw high land to the north-east, only about one hundred miles from the site assigned by Wilkes to his Termination Land The most fully investigated locality in the newly discovered Kaiser Wilhelm's Land is the Gaussberg, a basalt mountain on the southern shore of the bay in which the *Gauss* reached its farthest south

[1] "Deutsche Südpolar Expedition 1901–1903" Edited by Erich von Drygalski II Band Kartographie Geologie, Heft I Pp 87, 1 map, 8 plates. (1) E von Drygalski Der Gaussberg, seine Kartierung und seine Formen (2) E Philippi Geologische Beschreibung des Gaussberges. (3) R Reinisch Petrographische Beschreibung der Gaussberg Gesteine (Berlin G Reimer, 1906) Price 18 marks

The first part of the second volume of the expedition reports is devoted to a full description of the geography and geology of the Gaussberg. It includes three memoirs. A detailed account of the geography of the mountain is given by Prof. von Drygalski, in which he describes its form, position, and glaciation. The most interesting part of von Drygalski's report deals with the glaciation and the forms of the mountain. The inland ice from Antarctica abuts against the southern slope of the Gaussberg, although as a rule its junction with the inland ice is hidden by ice of local origin. The mountain is 370 metres in height, and it was at one period completely over-ridden by ice from the south, and the admirable photographs which accompany Dr. Philippi's report illustrate the subdued glaciated contours of the whole mountain. Some moraines occur on it, and indicate transport from south to north.

The valleys upon the flanks of the Gaussberg are not due to erosion, but are depressions between the lava streams or along lines of rapid weathering. In his description of the mountain, Prof. von Drygalski obviously writes with great restraint to prevent infringing on the geological report contributed by Dr. Philippi, whose memoir is accompanied by a series of excellent photographs of the mountain, its moraines and its lavas. The whole mountain is composed of volcanic rocks, which are described in full petrographic detail, accompanied by analyses and illustrations, by Dr. R. Reinisch, of Leipzig. The rocks are leucite-basalts and leucite-basalt tuffs, rich in glass. The only other indigenous rocks occur as inclusions in the lava; they are nodules of olivine and fragments of pyroxene-gneiss and pyroxene-granite, which appear to indicate that a platform of plutonic rocks occurs at a comparatively slight depth below the basalts.

FIG. 1.—Edge of the Inland Ice and Moraines at the north western corner of the Gaussberg.

The age of the mountain is doubtful, but appears to be late Cainozoic. Dr. Philippi suggests that the eruptions may have begun in the Pliocene, and, in his opinion, they were either late Pliocene or Pleistocene. The local glaciers Dr. Philippi describes as comparatively unimportant in their development. Erratic blocks from the inland ice that once covered the whole mountain are scattered to its summit. The erratics include boulders of granites, gneiss, amphibolites and other crystalline schists, with some quartzites, sandstones, and conglomerates. They indicate the continental structure of the land to the south. The section of Dr. Philippi's report which is probably of most general interest discusses to which of the two coastal types this land belongs. According to Reiter's well-known suggestion, Wilkes' Land is of the Atlantic type, while Victoria Land, as the continuation of the New Zealand line, is of the Pacific type. The evidence available from Cape Adare and Kaiser Wilhelm Land suggests that all the intervening coast is of the Atlantic type. According to Dr. Philippi, Victoria Land is the same. His conclusion rests on two considerations. Firstly, Victoria Land is a plateau land, and when Suess originally distinguished the Atlantic and Pacific coast-types he regarded coastal plateaus as confined to the Atlantic type. The coast of northern Queensland is, however, in part a plateau edge, but it may be retained in the Pacific type, as its characters have probably been determined by a succession of step faults parallel to the coast, a structure which Prof. Suess describes as characteristic of the Pacific type.

No doubt these inner step-faulted coasts of the off-lying seas of the Pacific are younger than the outer folded coast of the main ocean, and it may be convenient to separate them as secondary Pacific coasts. If so, then Victoria Land may be described as having a secondary Pacific coast, like the southern end of New Zealand and the eastern coasts of Australia, and the outer folded Pacific coast may then have passed from the middle of the South Island of New Zealand eastward towards Graham's Land along a line which is still unknown, and has perhaps been completely destroyed.

Unless the Pacific coast type is to be so re-defined as to assign an Atlantic structure to much of the Pacific coast, no adequate tectonic reason has been yet advanced for the removal of Victoria Land from the Pacific group. The second argument for this step is petrographic. Becke and Prior have both suggested that the Pacific and Atlantic types of coasts are characterised, not only by different tectonic structures, but by different groups of volcanic rocks. The volcanic rocks erupted along the Pacific folds are richer in silica, alumina, soda, and magnesia, and the volcanic rocks discharged from the fractures along the Atlantic shores are richer in potash, lime, and iron oxides. The characteristic volcanic rocks of the Pacific are rhyolites, dacites, andesites and acid basalts. Those characteristic of the Atlantic are trachytes, phonolites, tephrites, and basic basalts. The affinities of the volcanic rocks of the southern end of New Zealand and of Cape Adare are with the Atlantic group. As a rule, the distribution of Becke and Prior's petrographic types coincides to a remarkable extent with Suess's two tectonic divisions of the coasts of the world, but the petrographic and tectonic features do not appear to coincide universally, and it is doubtful whether the former is as suitable a taxonomic character as the other.

The Gaussberg area, situated as it is at the western end of Wilkes Land, is of such special interest that it is unfortunate that circumstances prevented the German explorers from reaching a wider extent of land; as these memoirs show the high quality and thoroughness of their work.

J. W. G.

COTTON CULTIVATION IN THE UNITED STATES OF AMERICA

A RECENT event the results of which may be of far-reaching importance was the visit of the commission appointed by a number of representative cotton-spinners "to make inquiry on the spot so as to ascertain, as nearly as possible, the cost of growing cotton, and the economic conditions under which it is produced in the cotton belt of the United States of America, also to investigate the methods of ginning, baling, marketing, and transport of the product"

The report of the commissioners is of great interest as affording a critical survey of the methods of cotton cultivation practised in the United States, regarded from the standpoint of the spinner Moreover, the fundamental problems facing cotton-growers in all parts of the world are essentially similar—to obtain the greatest quantity of good-quality cotton at the lowest cost, to keep in check pests, and to market the product in the best condition

The lines along which these problems have been, or are being, solved in the country which at present produces some three-quarters of the world's total commercial cotton crop are of the greatest practical interest in all cotton-producing countries, actual or potential, because the average price at which American cotton can be placed on the market is the ultimate standard of comparison for their own efforts

It is clear, in the first place, that the United States suffer no restrictions from want of suitable land Texas alone is estimated to possess sufficient land to produce annually 30,000 000 bales[1] of cotton The average commercial crop of the world is now about 17,000,000 bales, to which the United States contribute 10,600,000, Texas producing about 3,000 000 bales Labour conditions in the cotton belt, as well as the recent movement in favour of "diversified farming," are opposed to great extension of the acreage under cotton, and a larger output would appear to depend on increased production per acre

SEED SELECTION —The first place in the practical methods proposed to attain this end is given to seed selection To those acquainted with the work of Dr Webber and other officers of the U S Department of Agrict [illegible] and the wonderful activity of the department [illegible] nating agricultural literature and advic [illegible] t surprising to find that "this is a po [illegible] ttle attention has been paid, no do [illegible] of knowledge," but, as is pointed [illegible] nnection, the small negro farmer still grow [illegible] portion of the crop, and "it is difficult adequ [illegible] to describe the slip-shod and primitive methods which he employs" It must be remembered, too that this report does not deal with "Sea Island" cotton, and that the careful work on seed selection which has made the cottons from Colonel Rivers's and other estates world famous is not under criticism

Seed selection conducted on trial plots in an experiment station or in a nursery with a trained staff is tedious and arduous enough, but the practical difficulties are increased a hundredfold on estates with labour of a low order of intelligence Other practical obstacles are also encountered The first picking is generally regarded as yielding the best seed, but frequently the farmer has mortgaged his crop and sold in advance both seed and lint of the first and second pickings, and uses seed from the third and worst picking from which to raise the next year's crop Advances have, however, been made, and two general principles are enunciated Where labour is abundant the aim should be to select plants maturing over a comparatively long period and giving a large number of pickings Where labour is scarce the selection should be of plants which ripen all their bolls as nearly as possible at the same time Two examples are quoted "Texas Oak" (said to give the greatest yield of upland cotton) gives 10 per cent of the total yield at the first picking and 40 per cent at each of the second and third pickings On the other hand, the variety "King" yields 40 per cent at the first and another 40 per cent at the second picking only a fortnight later

[1] The weight of a bale of cotton is taken throughout as 500 lb

FERTILISERS —In the eastern States (North and South Carolina, Georgia, and Alabama) of the cotton belt careful attention has been directed to the use of manures, encouraged, it is suggested, by the phosphatic deposits in the neighbourhood of Charleston Between 1879 and 1905 the average yield per acre in these States increased by 35 2 per cent, whilst in the western States the increase during the same period was only 4 2 per cent

CULTIVATION —The negro farmer appears to be largely responsible for the very slow progress effected in this direction Much land is still cultivated on the "share system," with all its consequent disadvantages Improvements in cultural implements have been very rare, and the great desideratum is still an efficient cotton-picking machine, this operation alone costing now about 2¼ cents per lb of lint—practically a quarter of the total cost of production

PESTS —The cotton boll weevil (*Anthonomus grandis*) is the most serious of all the American cotton pests It now infests about one-third of the cotton area, is advancing at the rate of fifty miles per annum, and reduces the crop to about one half in attacked areas The loss due to it in Texas alone in 1904 was estimated at 22 000,000 dollars Clean cultivation, the burning of old plants, and the establishment of early maturing and resistant varieties by seed selection work appear the most promising methods for dealing with this formidable pest

GINNING —The saw-gin, first invented by Whitney more than a century ago, still holds the field by virtue of its large output, although its defects are well recognised Interesting information is afforded on other types of gins, still more or less in the experimental stage

BALING —The bad qualities of the American cotton bale are notorious, and the commissioners quote as "none too severe" Judge Ogden's description of it at the Washington Conference of Spinners and Planters in May last as "a dirty, damaged, disreputable, water-soaked, wasteful, slovenly, clumsy, highly inflammable, turtle-backed package"

The American bale has a density of only 22 lb per cubic foot, as opposed to 37 lb and 56 lb for Egyptian and Indian bales respectively A bale with a density of about 40 lb per cubic foot is recommended, and other improvements advocated in regard to packing, &c, which, if carried out, would, it is estimated, result in a saving of about 1,000 000*l* annually, chiefly in cost of freight

The principal recommendations and criticisms contained in the report are worthy of serious consideration in all countries engaged in the cultivation of cotton An effort may soon be made to put them into practice in the United States, as owing to the action of the cotton growers' associations in attempting to control supplies, a proposal is under consideration for English spinners to establish plantations in the cotton belt, and a second commission has already left England to select a suitable scene of operations

NOTES

THE prevalence and treatment of insanity have been the subject of much consideration recently, but it appears from a letter by Prof Clifford Allbutt in Wednesday's *Times* that though our system of public asylums is honourable and humane in intention, it is in a scientific sense, a gigantic muddle In fact, our management of insanity is, scientifically, a chaos "Muddle! In England, and in England alone, we muddle with complacency Now to muddle is to labour with effects without regard to causes Thus it is that we strive with the 'unemployed', thus that we strive with commercial incapacity, thus that we strive with educational failures, and so forth, 'compromise' being with us not the word for adaptations but for supineness We pile up hospitals, sanatoriums, sick asylums, homes for incurables, colonies for epileptics and idiots, at vast cost direct and indirect, and wealthy persons make bequests, sometimes even liberal bequests, to such purposes; but what testator leaves money to an organisation of research by physicians and pathologists into the sources from which this frightful and manifold destruction pours forth with an absolutely, and perhaps with a relatively, augmenting volume? (I must not seem to forget the Lister Institute or recent gifts to the Cancer Fund, but of the general truth of my statement your own reports of bequests from day to day are sufficient testimony) No wonder that, thus ignorant but beginning to 'wake up,' we run to the nearest plausible short cuts—to quackery and to hand-to-mouth remedies which are no remedies—rather than to the laborious investigation of origins and accelerations If fifty years ago a tithe of the money expended upon the charities which are fighting at heavy odds with consequences had been spent upon knowledge, and this knowledge had been applied to prevention by a Ministry of Health instead of, as in its present imperfection, by a secondary department of some other office, by this time half of our expenditure on these melancholy results of our ignorance would have been saved, and the saving would be rapidly multiplying itself" Prof Allbutt urges that hospitals should be established for research into diseases of the nervous system certain wards or wings being provided for the insane The staff of a hospital of this kind should consist of young physicians intellectually mature and highly and variously trained Only when continuous and critical observations have been made under scientific conditions will it be possible to begin to create a classification of diseases of the nervous system by pathological affinity to displace the classifications which now are admirable only or chiefly for logical and metaphysical ingenuity

DR N L BRITTON, director of the New York Botanical Garden, has been elected president of the New York Academy of Sciences

A PAPER by the Duke of the Abruzzi upon his expedition to Mount Ruwenzori will be read at a special meeting of the Royal Geographical Society on Saturday, January 12

MR SYDNEY S HOUGH, F R S, chief assistant in the Royal Observatory, Cape of Good Hope has been appointed His Majesty's astronomer at that observatory on the retirement of Sir David Gill, K C B, F R S

THE honorary treasurer of the Imperial Cancer Research Fund has received from Mr and Mrs Bischoffsheim the munificent donation of 40,000*l* on the occasion of the celebration of their golden wedding

AT the annual banquet of the Institute of Chemistry of France a few days ago, it was announced in the name of the Minister of Public Instruction that the French Government has drawn up a decree giving academic recognition to the profession of chemical engineer

THE *Kew Bulletin* announces that Captain A T Gage has been appointed superintendent of the Royal Botanic Gardens, Calcutta, and director of the Botanical Survey of India We learn from the same source that Dr D H Scott, F R S, has relinquished his post of honorary director of the Jodrell Laboratory, Kew, which he has filled with great distinction during the past fourteen years

A MOVEMENT has been inaugurated by the professors of the National Museum of Natural History in Paris, with the approval of the Minister of Public Instruction for the erection of a statue of Lamarck in the Jardin des Plantes Subscriptions to the fund which is being raised may be sent to M Joubin, secretary to the committee, 55 rue de Buffon, Paris

THE Aëro Club has arranged for an exhibition in connection with the International Motor-car Exhibition to be held at the Royal Agricultural Hall, London from April 6–13 next Prizes to the value of 250*l* are offered by the proprietors of the *Daily Mail* for model flying machines, and full particulars as to the conditions of the competition may be obtained from Mr Harold E Perrin Aero Club, 166 Piccadilly, London, W

IT is stated in *Engineering* of December 28 1906, that the German Railway Union has presented to the Science Museum at Munich an exact reproduction of "Puffing Billy," the oldest locomotive in existence, now preserved in the Victoria and Albert Museum The Munich engine is an exact counterpart of the original, and has been tested under steam, when a train load of 38½ tons was hauled at upwards of six miles per hour The work was carried out at the central shops of the Royal Bavarian State Railways at Munich

WE learn from *Science* that Prof H F Osborn has declined the secretaryship of the Smithsonian Institution to which he was elected by the regents on December 4, 1906 In a letter to the Chancellor of the institution, Prof Osborn explains why he is unable to accept the post of secretary Chief among these reasons is the fact that he is nearing the completion of several monographs and books, the prosecution of which is dependent upon the collections which he has brought together in New York and the staff of trained assistants who are working with him

A SPECIAL report from Berlin in the *Pall Mall Gazette* of December 28 1906, described some wireless telephony experiments which have been made by Prof Slaby, who claims to have solved successfully the problem of wireless telephony which has been so often attempted The trials took place over a distance of forty kilometres between the headquarters of the Wireless Telegraph Co in Berlin and the wireless station at Nauen The microphone was connected to a wire rising about six metres above the roof, and both figures and a sentence of extreme phonetic difficulty were received and repeated back without error and very clearly heard Prof Slaby claims that no approach to forty kilometres has ever been tried before, and that his success is due to the isolation of the microphones and the "damping" of all foreign vibrations We do not know the greatest distance over which Mr Paulsen has successfully conducted his wireless telephony and we shall wait with interest to see what developments may

take place very shortly, as some marked advance may surely be expected when the results of the experiments of two such investigators as Prof. Slaby and Mr. Paulsen become fully known.

THE recent experience of the London County Council tramways under Arctic conditions has not strengthened the arguments of those sections of the public and engineers who are all for the abolition of the overhead system in favour of the underground conduit system. Granted that the conditions which caused the serious interruption of traffic last week are not usual and were not expected, it is still hard to account for the unpreparedness of those in charge of the London County Council tramways. In happy contrast to this comes the news of the capabilities of the overhead system in Liverpool, where not only was the service maintained without mishap, but the trams were of great assistance in clearing away the snow by drawing trollies of salt over the city, thus enabling the salt to be distributed rapidly, and making it easy work for the firemen to wash down the streets afterwards. Wolverhampton also suffered by not having an overhead system of tramways, and the service had to be discontinued. We have not yet heard of any case where an overhead system of tramways in England has failed owing to the recent snow, so that, at a time when the telegraph wires are being broken down by snow and by the force of the gales we have been experiencing lately, it speaks well for modern overhead tramway practice that it should have passed through the ordeal so successfully, and once again helps to prove that the supposed dangers and disadvantages of the overhead system are more fancied than real.

A CORRESPONDENT, writing from Torbay, states that on December 29, 1906 (full moon), and more particularly on December 30, from 10 p.m. to 11.30 p.m., she observed a remarkable lunar halo. The moon appeared in the centre of a pellucid patch of sky enclosed by the halo, which measured at least four times the moon's apparent diameter, and in this clear sky, as in a mirror, our correspondent saw a reflection of the moon.

WE learn from the *Pioneer Mail* that the Dooars' Planters' Association recently discussed the subject of malaria and black-water fever. The meeting viewed with great concern the alarming prevalence of malaria and black water fever in the western Dooars, and was of opinion that all possible steps should be taken to inquire into these diseases with a view to check them. The association is convinced that the report of the commission on malaria to the Royal Society dated 1902 goes to the root of the evil, and that the Anopheles mosquito, which is found in large numbers in the Dooars, is the cause of the prevalence of malaria and black water fever, and that no time should be lost before tackling the question scientifically. As a preliminary, the Indian Tea Association of Calcutta and London is to be asked to move in the matter, and the association will also address the local Government and the Government of India on the subject, and the Home Government through the Tea Association.

THE most important item in the November (1906) issue of the *Victorian Naturalist* is a paper by Prof. Baldwin Spencer on emu remains from King Island, Bass Strait. Definite information as to the former existence of an emu on this island is to hand, and since the bones recently discovered indicate a bird of smaller size than *Dromaeus ater* of Kangaroo Island, the name *D. minor* is proposed for the new species.

WE have to acknowledge the receipt of a copy of part ii (vol. i.) of the new journal *Experimentelle Beiträge zur Morphologie*, published at Leipzig, and edited by Mr. Hermann Braus, of Heidelberg. In the first article Mr. O. Bender describes a case of "hypermelism" in an edible frog, in which the abnormality takes the form of an additional hind limb, and discusses the morphological conclusions to be drawn therefrom. The second article, by the editor, is devoted to the mode of development of the fore-limb and operculum in the larva of the fire-bellied toad (Bombinator).

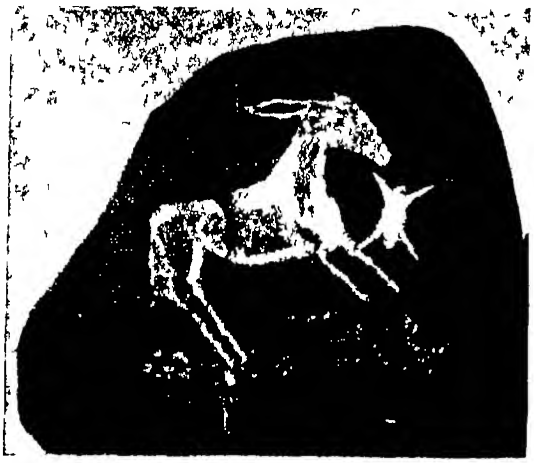
"SOME Problems of the Sea" forms the title of the presidential address delivered by Prof. Herdman to the meeting of the Liverpool Biological Society held on October 26, 1906. After alluding to the frequent periodical local variation in the constituents of the plankton and the endeavours which have been made to ascertain the actual or relative numbers of organisms inhabiting a given area in the sea, the president proceeded to institute a comparison between the littoral fauna of Ceylon and that of the Maldive Archipelago. In explanation of certain differences of these two faunas, it is suggested that it may be easier for a shallow-water, non-pelagic species to reach Australia from India by way of Malaysia rather than cross the open sea separating Ceylon from the Maldives.

THE first part of the sixth volume of *Annotationes Zoologicae Japonenses* opens with an account of a new Japanese salpeid provisionally referred to the genus Cyclosalpa, by Mr. W. E. Ritter. Although only a single specimen, taken in Suraga Bay, is forthcoming, this is amply sufficient to demonstrate the marked distinctness of the new form. Until examples of the aggregate generation are available, the full affinities of the species cannot be determined. Its most obvious features are the straight intestine, the great number of the muscle-bands, which exceed those of all other forms except one Salpa, and the fact that many of these bands extend right round the body. In the latter respect the new form tends to minimise the differences separating the Doliolidæ from the Salpidæ. The other papers in the same issue deal respectively with Japanese butterflies, cockroaches, and ascidians.

SINCE very little is known in regard to the segmentation of the ovum among mammals, workers in embryology should welcome a paper by Mr. M. Kunsemuller in the *Zeitschrift fur wissenschaftliche Zoologie*, vol. lxxxv., part 1, on this stage of development in the hedgehog. Comparisons are made between the segmentation in this species and other mammals in which it has been observed. A second article in the same issue deals with the early stages in the development of the grass-snake, from the first appearance of the pro-amnion to the close of the amniotic stage. The paper ends with a *résumé* of the present state of our knowledge of snake-development, which is still very imperfect. Regeneration in polychæte worms forms the subject of the third article, by Mr. P. Ivanoff, of St. Petersburg. Apparently the article was written previous to the issue of Nusbaum's paper on regeneration in Nereis in vol. lxxix. of the same journal, but its publication was delayed by the necessity of translation. Some of the author's conclusions have thus been anticipated. Among other curious examples of regeneration, Mr. Ivanoff mentions one case in which an annelid developed a complete functional head at each extremity of the body. In the fourth article Mr. F. Vejdovsky resumes his discussion of the hæmacœle theory as illustrated by the vascular system of worms.

WITH regard to the naming of plants of Lessonia received from the Antarctic region, Mr. and Mrs. A. Gepp note in the *Journal of Botany* (December, 1906) that anatomical investigation discloses a distinction between the specimens from Cape Adare and Coulman Island and that from the South Orkneys. The former receives the name of *Lessonia grandifolia*, the latter *L. simulans*.

IN vol. xvi. of the Transactions of the South African Philosophical Society is a paper by Mr. L. Péringuey on petroglyphs of animals and men in South Africa considered in relation to those found in northern Africa. He points out that two kinds of workmanship are found in Algeria and the Sudan—line engraving and dot engraving, the former being apparently much older, as prehistoric animals now extinct, such as *Bubalus antiquus*, are represented with great fidelity. Similar differences of technique exist in South Africa, and the author argues that they afford evidence of a pre-Bushman race akin to the aborigines of the north, but he is evidently a zoologist, not an anthropologist, and it is clear that more material is needed for comparison, as well as definite archæological data, before the views set forth in this paper can rank as



Rock engraving (chalked to show clearly) of a Gemsbok checking itself while at full speed.

more than mere conjectures. The article is well illustrated by ten figures, of which one is reproduced here; the author remarks that it represents a gemsbok checking itself at full speed before an object intended to alarm it, but it does not seem necessary to assume more than a chance connection between the figures. The petroglyphs were chalked over for photographic purposes; this introduces an element of uncertainty which it would be well to eliminate.

ON the subject of diseases of palms Mr. E. J. Butler contributes a paper to the *Agricultural Journal of India* (vol. i., part iv.) recording three diseases that have come under his observation in India. In the first case the inflorescences of betel-nut palms were destroyed by a Phytophthora causing what is locally known as "kale roga," or black rot; in another a bud-rot disease of palmyra and cocoa-nut palms in the Godavari district was traced to a Pythium. The so-called betel-nut plague occurring in Sylhet was more difficult to diagnose, but the author refers it definitely to a fungus attacking the roots, and the clamp connections in the mycelium point to its being a basidiomycete. Detailed descriptions are given and remedial measures suggested.

THE latest addition to the series of German pamphlets on the pedagogics of the natural sciences published by B. G. Teubner of Leipzig, deals with the subject of a scheme for teaching nature-study in schools. The author, Dr. P. Henkler, reviews several schemes advocated by masters of pedagogy and instructors in natural history before elaborating his own syllabus. During the first stage for small children, extending over three courses, it is suggested that interest in natural objects should be aroused by imaginative or personified presentment, and observation be coordinated with facts of everyday life. In the second stage botany and zoology would be taught as independent subjects, the essential idea being to stimulate the faculty of inquiry by studying purpose and cause.

MR. MALCOLM BURR has written for the Kent Coal Concessions, Ltd., a popular introduction to the study of the geology of the south-eastern coalfield. It contains in simple language a concise explanation of the principles of geology sufficient to enable shareholders to follow intelligently the significance of the various borings carried out under the auspices of the company.

IN the *Engineering Magazine* (vol. xxxii., No. 3) there is an admirably illustrated article by Mr. Frank L. Hess on the York tin region of Alaska, where lode tin was discovered in 1903. Should the lode deposits be shown to contain sufficient tin to pay for working, they will have many advantages over placer deposits, inasmuch as mining would not have to be confined to the short open season.

THE Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol. l., part ii.) contains an interesting paper by Mr. Hugh Campbell on suction gas engines. The introduction of the suction gas plant invented in 1894 is causing a greater revolution in practice than has occurred in connection with the development of large gas engines which are mainly used at the present time in conjunction with blast-furnace gas. Its very high economy, extreme simplicity, its cleanliness, and the small amount of space it occupies are sufficient to commend it to power users.

A PAPER read by Mr. Henry Fowler before the Institution of Mechanical Engineers on December 14, 1906, dealing with the lighting of railway premises, contained much information of value to engineers generally. The lighting on a railway is chiefly provided by means of oil, gas, or electricity, gas being probably the most general illuminant. In most places it has been able to hold its position owing to the introduction of incandescent mantles. The cost of maintaining an incandescent mantle for a year to June, 1906, is shown to have been as follows:—mantles 5.20*d.*, chimneys 1.27*d.*, forks 0.33*d.*, and wages 1*s.* 4.16*d.* per annum.

IN a recent note (p. 181) attention was directed to the recent renewal of experiments with Count Zeppelin's latest airship on the Lake of Constance. An account of these new experiments is given by Dr. Wilhelm Krebs in *Das Weltall* for December 15, 1906. The 1906 Zeppelin airship, like its forerunners, consists of eighteen separate compartments or separate balloons supported on a rigid cylindrical aluminium framework, the whole being enclosed in a covering of balloon silk. The rigidity being secured by the framework, the use of an internal "ballonet" is dispensed with. The whole airship is 128 metres long by 11 metres high, and each of the two cars can hold four persons, besides having a separate motor. The author states that with both motors working simultaneously a

speed of 15 metres per second, or 54 kilometres per hour, can be maintained for sixty hours with the quantity of benzene the machine will carry With one motor alone working a speed of 11 metres per second would be maintained for 120 hours The advantages of the Zeppelin airship are more or less counterbalanced by the present necessity of using a sheet of water for starting and landing Apart from the uses of such a machine in warfare, its applications in time of peace to the meteorological survey of the atmosphere are contemplated

AN interesting but highly mathematical memoir by Prof Karl Pearson and Mr J Blakeman on "A Mathematical Theory of Random Migration" has just been issued by Messrs Dulau and Co (Drapers' Co research memoirs, biometric series, iii) The problem dealt with is, in simple terms, the following —given that a large number of individuals move by successive straight steps of length l in random directions, starting from one and the same point, required to find their distribution after n such steps The solution, which is obtained in terms of Bessel functions, is applicable to such practical problems as the infiltration of mosquitoes into a cleared area, or the recovery of a habitat by a species which has been driven out owing to temporarily unfavourable conditions Prof Pearson obtained some assistance in the solution of the problem through a letter addressed to our correspondence columns (vol lxxii p 294, July 27, 1905), Lord Rayleigh directed his attention (*ibid*, p 318) to the fact that when the number of steps n is very large, the problem becomes identical with a problem in sound, and Prof Kluyver presented a memoir on the subject to the Royal Academy of Sciences of Amsterdam (Proceedings, October 25, 1905) Reference should, we think, have been made, in the introduction to the memoir, to the address delivered by Major Ross "On the Logical Basis of the Sanitary Policy of Mosquito Reduction" at the St Louis Congress of 1904 (*British Medical Journal*, May 13 1905) This contains the first published discussion of the problem, with especial reference to its most important practical application and suggests a simple approximate solution in terms of the binomial series

AN investigation of the temperatures obtainable by the use of solid carbon dioxide under different pressures forms the subject of a paper by Messrs John Zeleny and Anthony Zeleny in the *Physical Review* (vol xxiii, No 4) In a deep vessel of such a shape that the material is surrounded by its own vapour, the same temperature is given under any one pressure by the carbon dioxide either alone or when mixed with alcohol or ether, it is, however, more easy to maintain the temperature constant when the solid is moistened with ether A table is given showing the temperatures obtainable by varying the pressure above the solid from 2 cm to 84 cm of mercury At the former pressure the temperature is $-116°7$, and at the latter $-77°$ C

SOME very remarkable results have been obtained by Prof R W Wood in the course of an investigation of the fluorescence and magnetic rotation spectra of sodium vapour, published in the Proceedings of the American Academy of Arts and Sciences (vol xlii, No 13), and also in the *Physikalische Zeitschrift* (No 24) The fluorescence spectra were observed using monochromatic light of a definite wave-length as source of excitation Different series of lines are seen with different exciting wave-lengths The series are mostly of a very simple character, consisting of groups of lines separated by a constant wave-length The same series of lines are also observed in the magnetic rotation spectrum of sodium vapour, which can thus be subjected to analysis Certain lines, however, which occur singly in the magnetic spectrum occur as doublets in the fluorescence spectra The detailed measurements obtained, from the comparative simplicity of the phenomena, are likely to prove of very great importance in discussing the mechanism of molecular vibration and radiation

FROM the dissociation theory of solution it might be inferred that as the radiation from a radio-active substance renders a gas conducting by causing ionisation of the gaseous particles, an increase of the conductivity of aqueous solutions should follow from their exposure to radio-active influence The effect in the latter case should, indeed, be very marked inasmuch as partial ionisation of a salt occurs merely on dissolving it in water, whereas in the case of a gas ionisation takes place only under special influences The conductivity of a large number of salts in aqueous solution has been measured by M S M Sabat (Bulletin of the Cracow Academy of Sciences, 1906, No 1) during their exposure to the radiation produced by 0 2 gram of Prof Curie's most active preparation of radium bromide After making allowance for the alteration of resistance caused by the rise of temperature due to the radiation, the conclusion is drawn that not the slightest change in conductivity can be attributed to a change in the degree of ionisation of the salt within the solution If such a change of ionisation takes place it is so slight as to be altogether negligible

MR DAVID NUTT has published for the Folk-lore Society a "Bibliography of Folk-lore" for 1905, which has been compiled by Mr N W Thomas The price of the booklet is 1s net

MESSRS J AND A CHURCHILL have published a third edition of "A Handbook of Physics and Chemistry adapted to the Requirements of the First Examination of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons and also for General Use" by Messrs Herbert E Corbin and Archibald M Stewart

WE have received a copy of the report of the Meteorological Service of Canada for the year ended on December 31, 1904 In nearly four hundred foolscap pages Mr R F Stupart, the director, has brought together results of observations of the temperature, pressure, rainfall, snowfall, amount of bright sunshine, and other meteorological data concerning all parts of Canada The volume also includes the magnetic results for each month and for the year 1904

IN his work "Erkenntniss und Irrtum," reviewed in NATURE of November 30, 1905 (vol lxxiii, Supp, p vii) Prof E Mach partly included three essays in which the questions of the nature, origin, and development of our concepts of space were discussed from several points of view The English rendering of these essays, which originally appeared in the *Monist*, has now been published in volume form by Messrs Kegan Paul and Co, Ltd, under the title "Space and Geometry in the Light of Physiological, Psychological, and Physical Inquiry"

IN NATURE of October 11, 1906 (vol lxxiv, p 594), reference was made to a paper by Prof Kamerlingh Onnes and Dr Heuse on the expansion of glass at very low temperatures, and attention was directed to the work of Dr Travers on the same subject Prof Onnes writes to point out that the memoir referred to was a translation of a Dutch paper, published somewhat earlier than that of Dr Travers, to which we alluded, and that in a more recent communication on the same subject he has not failed to recognise the results obtained by this investigator

OUR ASTRONOMICAL COLUMN

COMET 1906g (THIELE).—From observations made with the Lick Observatory 12-inch refractor, Messrs. Aitken and Fath have computed a set of parabolic elements for Thiele's comet. These elements, together with an ephemeris extending to January 19, appear in No. 103 of the Lick Observatory Bulletins, and give the time of perihelion passage as 1906 November 21. The comet is at present (January 3) about 5 m. east of ι Draconis, and is travelling nearly due east, its brightness being about one-half that at the time of discovery (mag. 8·5).

THE LUNAR CRATER LINNÉ.—In a recent number of the *Astronomische Nachrichten* Dr. Wirtz pointed out that an apparent enlargement of the white spot surrounding Linné could be produced by interposing a shade-glass between the telescope and the eye, and from this fact he argued that the enlargement of the spot observed during a lunar eclipse might be merely a subjective phenomenon due to the diminution of light.

In No. 4141 of the same journal Prof. W. H. Pickering points out that whilst this apparent enlargement, which Dr. Wirtz describes, undoubtedly exists, its magnitude is much less than that recorded by the eclipse observers. Furthermore, the majority of the eclipse observations indicate that the white spot was decidedly larger after the passing than at the same length of time before the encroachment of the earth's shadow, whereas if the enlargement were merely a subjective effect it should not survive the re-illumination. The fact that Dr. Wirtz has observed similar results in the case of the crater Linné B is not regarded by Prof. Pickering as an argument against their reality, for if the phenomenon is due to the deposition of hoar-frost it should, *ceteris paribus*, be general over the moon's visible surface, and he has himself obtained similar results for Sulpicius Gallus A (*Astronomische Nachrichten*, No. 4141).

EPHEMERIDES OF COMETS AND PLANETS.—With the commencement of the new year the editors of the *Astronomische Nachrichten* are issuing the ephemerides of comets and planets in a separate publication called the *Ephemeriden-Zirkular der Astronomischen Nachrichten*. The annual subscription is 10 marks, and orders should be addressed directly to the "Expedition in Kiel, Niemannsweg 103."

A RÉSUMÉ OF AREOGRAPHY.—In No. 22 (1906) of the *Revue générale des Sciences*, L'Abbé Th. Moreux discusses the present state of our knowledge of Mars especially in reference to the more recent observations of Prof. Lowell and other aerographers, although in the first part he details the work of the earlier observers, Herschel, Beer and Madler, Secchi, Lockyer, Kaiser, and others. Whilst agreeing with Lowell as to the bolder features, M. Moreux evidently entertains very grave doubts as to the objective reality of many of the fine rectilinear *canaux* of which the former observer has recorded 420, and further states that he has never seen the alleged *oases* which are said to mark their intersections.

M. Moreux also discusses the gemination of the canals at some length, and then gives in detail the results of his own observations during the opposition of 1905, giving a number of drawings and a chart to illustrate his points. From these observations he is convinced that the persistent transparency of the Martian atmosphere has been overrated in the past. To illustrate this conviction he gives instances of cloud formations blotting out the detail locally, on the planet's surface.

JUPITER'S SATELLITES.—No. 4143 of the *Astronomische Nachrichten* contains an ephemeris for Jupiter's sixth satellite, computed by Mr. J. F. Martin, of Washington, from unpublished elements derived by Dr. Ross. The ephemeris extends to April 17, 1907, and gives the differences (Satellite–Jupiter) in α and δ, and the position angle and distance from the planet for every fifth day.

In the same journal Herr K. Graff records the observation, on September 24, 1906, of the occultation of an 8·5 magnitude star by Jupiter's third satellite.

THE CAUSES OF SOLAR PHENOMENA.—We have received from Don Horacio Bentabol y Ureta, of Madrid, a monograph dealing with the causes which produce spots, prominences, faculæ, &c., on the sun. The discussion is too lengthy to give the author's points *in extenso*, but he favours the meteoritic origin of the spots, and shows how the other solar, and the correlated meteorological, phenomena may be accounted for on this hypothesis.

PRIZES AWARDED AND PROPOSED BY THE PARIS ACADEMY OF SCIENCES.

AT the anniversary meeting of the Paris Academy of Sciences held on December 17, 1906, the president, M. H. Poincaré, announced that the prize awards for the year 1906 were as follows:—

PRIZES AWARDED.

Mathematics.—Grand prize in the mathematical sciences, divided between H. Padé (1500 francs), R. de Montessus (1000 francs), and M. Auric (500 francs), for their work on the convergence of continued algebraical fractions. The Francœur prize to Émile Lemoine, for his works on geometry. The Poncelet prize to M. Guichard, for the whole of his contributions to geometry.

Mechanics.—A Montyon prize to Georges Marié, for his study of the oscillations of railway carriages; the Boileau prize to Edmond Maillet, for his investigations on the yield of deep springs.

Navigation.—The extraordinary prize of 6000 francs, divided between MM. Daveluy, Rollet de l'Isle, J. Th. Saconney, and G. B. Girard; the Plumey prize to Prof. Stodola, for his work on steam turbines.

Astronomy.—The Pierre Guzman prize was not awarded. The Lalande prize to R. G. Aitken and W. J. Hussey, for their work on double stars; the Valz prize to J. Palisa, for the whole of his astronomical researches; the Janssen medal to A. Riccò, for his observations on the sun.

Geography.—The Tchihatchef prize to Jean Baptiste Louis Pierre; the Binoux prize to MM. Larras and F. de Larminat; the Delalande prize to L. Seurat, for his exploration of the islands near Tahiti.

Physics.—The Hebert prize to G. Gouré de Villemontée, for his researches on the conditions governing differences of contact potential; the Hughes prize to Daniel Berthelot, for his application of interference methods to the measurement of high temperatures and his researches on the compressibility of gases.

Chemistry.—The Jecker prize to M. Grignard, for his researches on the organo-magnesium compounds; the Cahours prize to M. Martine, for his work on menthone and menthol and their derivatives; a Montyon prize (unhealthy trades) to Victor Georgel, for his researches on leadless glazes.

Botany.—The Desmazières prize to Jules Cardot, for his researches on mosses; the Montagne prize to Émile Boudier, for his work on mycology; the De Coincy prize to E. G. Camus and Mlle. A. Camus, for their work on the classification and monography of the willows of Europe.

Anatomy and Zoology.—The Savigny prize to Paul Pallary, for his work on northern Africa and the Red Sea; the Thore prize to C. Houlbert, for his entomological work; the Gama Machado prize to Antoine Henri Mandoul and Pierre Stéphan (in equal parts).

Medicine and Surgery.—Montyon prizes to Paul Poirier and A. Charpy, for their work on anatomy; J. Albarran, for his work on renal functions; and Ch. Porcher, for his studies on lactosuria. Mentions are also accorded to Robert Lœwy, for his memoir on fractures; to Adolphe Javal, for his memoir on the treatment of Bright's œdema; and to MM. Guillemard and Moog, for their work on the influence of high altitudes on the general nutrition. Citations are accorded to Lucien Graux, Louis and Paul Murat, and A. Gougenheim. The Barbier prize to Adrien Lucet, for his memoirs on the bacteriology of suppuration in animals of the bovine species and on pathogenic moulds, with a mention to J. V. Detroye, for his work on cancers and tumours in animals. The Bréant prize to M. Rémy, for his quantitative studies on serums; the Godard prize to L. H. Farabeuf, for his monograph on the blood vessels of the genito-urinary organs; the Baron Larrey prize to Dr. Morel, for his memoir on epidemic and endemic diseases in the French colonies; the Bellion prize to Georges G.

Paraf, for his work on hygiene; the Mège prize to S. Turchini, for his experimental study on the power of the X-ray tube under different conditions of use.

Physiology.—A Montyon prize to E. Meyer, for his researches in experimental physiology from 1886 to 1904, a mention being accorded to J. Sellier for his researches on digestion and the digestive ferments; the Philipeaux prize to Stéphane Leduc, for the whole of his researches in experimental physiology, M. Caubert receiving a mention; the Lallemand prize to André Léri, for his clinical and anatomical researches on tabes; the Pourat prize to Georges Bohn, for his researches on phototropism; the Martin-Damourette prize to Lucien Butte, for his researches on the physiological and therapeutical action of Guaco (*Aristolochia cymbifera*), a very honourable mention being accorded to Pierre Sée for his study of the therapeutical applications of the oxydases and the metal ferments.

Statistics.—A Montyon prize to Dr. Ausset, for his memoir on the infantile mortality in the Département du Nord, a very honourable mention being accorded to Dr. Butte for his memoir on the statistics of syphilis in Paris, and an honourable mention to Dr. Ott for his work on infant mortality in the town of Lillebonne.

General Prizes.—The Lavoisier medal to S. M. Jorgensen, for his researches in inorganic chemistry; the Berthelot medal to S. M. Jorgensen and M. Martine; the Trémont prize to M. Frémont, for his experimental researches on metals; the Gegner prize to J. H. Fabre; the Lannelongue prize divided between Mme. Beclard and Mme. Cusco; the Jerome Ponti prize divided between M. Offret, for his work in mineralogy, and M. Gruvel, for his researches on the Cirrhipedæ; the Wilde prize divided between M. Termier, for his researches on the geological structure of the eastern Alps, and M. Massau, for his work in applied mechanics, and especially for his researches in graphical integration; the Saintour prize divided between Ant. Magnin, for his work in botanical geography, and I. Laurent, for his work in plant palæontology; the Houllevigue prize divided between G. André, for his researches in the physiological chemistry of plants, E. Bataillon, for the whole of his researches in experimental embryology, and A. Pizon, for his work on the development of the tunicates; the Cuvier prize to Dr. Raffray, for the whole of his work on insects; the Jean Reynaud prize to Pierre Curie, for his work on piezoelectricity and the properties of the radio-active bodies; the Baron de Joest prize to M. Demoulin, for his researches in infinitesimal geometry; the prize founded by the Marquise de Laplace to Paul Pierre Lévy; and the prize founded by M. Félix Rivot to MM. Lévy, Bélugou, Petit, and Lane.

PRIZES PROPOSED.

The subjects proposed by the academy for prizes for 1908 are as follows:—

Geometry.—The grand prize of the mathematical sciences (3000 francs). The question proposed for 1908 is the following:—to realise an important progress in the study of the deformation of the general surface of the second degree; the Francœur prize (1000 francs), for discoveries or work useful to the progress of the sciences of pure and applied mathematics.

Mechanics.—A Montyon prize (700 francs), for the invention or improvement of instruments useful to the progress of agriculture, the mechanical arts, or sciences; the Fourneyron prize (1000 francs), for a theoretical or experimental study of steam turbines.

Navigation.—The extraordinary prize of 6000 francs, for work tending to increase the efficacy of the French naval forces; the Plumey prize (4000 francs), for improvements in steam engines or any other invention contributing to the progress of steam navigation.

Astronomy.—The Lalande prize (540 francs), for an observation, memoir, or work most useful to the progress of astronomy; the Valz prize (460 francs), to the author of the most interesting astronomical observation made during the year; the Damoiseau prize (2000 francs), the question proposed is the theory of the planet Eros based upon known observations; the Janssen prize (a gold medal), for a discovery or work constituting an important progress in physical astronomy.

Geography.—The Gay prize (1500 francs), for geographical studies on Morocco; the Tchihatchef prize (3000 francs), for the exploration of the lesser-known regions of Asia, the work being done in any branch of science; the Binoux prize (2000 francs), for work in geography and navigation; the Delalande-Guérineau prize (1000 francs).

Physics.—The Hébert prize (1000 francs), for the best treatise or most useful discovery for the practical employment of electricity; the Hughes prize (2500 francs), for discoveries or works contributing to the progress of physics.

Chemistry.—The Jecker prize (10,000 francs), for work in organic chemistry; the Cahours prize (3000 francs), for the encouragement of young chemists; Montyon prize (a prize of 2500 francs and a mention of 1500 francs), for a discovery of a means of rendering an art or trade less unhealthy.

Mineralogy and Geology.—The Fontannes prize (2000 francs), for the best palæontological publication; the Bordin prize (3000 francs), for a study of the fossil fishes of the Paris basin.

Botany.—The Desmazières prize (1600 francs), for the best work during the current year on cryptogams; the Montagne prize (1500 francs), for work on the anatomy, physiology, development, or description of the lower cryptogams; the de Coincy prize (900 francs), for a work on phanerogams.

Anatomy and Zoology.—The Savigny prize (1300 francs), for assisting young travelling zoologists, with special reference to the invertebrate animals of Egypt and Syria; the Thore prize (200 francs), for the best work on the habits and anatomy of a species of European insect.

Medicine and Surgery.—A Montyon prize (prize of 2500 francs, mentions of 1500 francs), for work or discoveries useful in the art of healing; the Barbier prize (2000 francs), for a discovery in the surgical, medical, or pharmaceutical sciences, or in botany with reference to the art of healing; the Bréant prize (100,000 francs), for the discovery of a drug which will cure Asiatic cholera in the great majority of cases, or for indicating in an absolutely certain manner the causes of Asiatic cholera, so that by the suppression of these causes the epidemic can be stopped, or, in the alternative, for the discovery of a prophylactic treatment as certain as that of vaccination for small-pox. If the capital sum is not awarded, the interest will be given as a prize for a rigorous demonstration of the existence in the atmosphere of material taking part in the production or propagation of epidemic diseases. The Godard prize (1000 francs), for the best memoir on the anatomy, physiology, and pathology of the genito-urinary organs; the Baron Larrey prize (750 francs), for a work by an army or navy surgeon or physician treating of the subject of military medicine, surgery, or hygiene; the Bellion prize (1400 francs), for the author of works or discoveries "especially profitable to the health of man or the amelioration of the human species"; the Mège prize (10,000 francs); the Serres prize (7500 francs), for the best work dealing with general embryology applied as far as possible to physiology and medicine.

Physiology.—A Montyon prize (750 francs), for a work on experimental physiology; the Philipeaux prize (900 francs), for the same; the Lallemand prize (1800 francs), to recompense or encourage works relating to the nervous system; the Martin-Damourette prize (1400 francs), for work in therapeutical physiology; the Pourat prize (1000 francs), for a work on the immediate destination of the energy devoted to maintaining life in warm-blooded subjects.

Statistics.—A Montyon prize of 1000 francs and a mention of 500 francs.

General Prizes.—The Arago medal; the Lavoisier medal for services to chemistry; the Berthelot medal; the Trémont prize (1100 francs); the Gegner prize (3800 francs); the Lannelongue prize (2000 francs); the Wilde prize (one of 4000 francs or two of 2000 francs); the Victor Raulin prize (1500 francs); the Saintour prize (3000 francs); the prize founded by Mme. la Marquise de Laplace; the Félix Rivot prize (2500 francs); the Jerome Ponti prize (3500 francs); the Houllevigue prize (5000 francs); the Estrade-Delcros prize (8000 francs).

Of these prizes, those bearing the names of Lalande, Tchihatchef, Desmazières, Lavoisier, and Wilde are expressly stated to be free from any restriction as to nationality.

RECENT WORK OF THE AMERICAN BUREAU OF STANDARDS

PART 1 of vol II of the Bulletin of the Bureau of Standards of the United States contains five papers The first of these is by Mr Hyde, on Talbot's law as applied to the rotating sectored disc The law is stated by Helmholtz as follows —" If any part of the retina is excited with intermittent light recurring periodically and regularly in the same way, and if the period is sufficiently short, a continuous impression will result, which is the same as that which would result if the total light received during each period were uniformly distributed throughout the whole period "

Much experimental work has been done on the subject leading to somewhat conflicting results. After a theoretical discussion Mr Hyde describes his own experiments, from which he concludes —

(1) Talbot's law is verified for white light for all total angular openings from 10° to 288° to within a possible error of 0 3 per cent

(2) The observed deviations from the law for red, green, and blue light are of the same order as those for white light

The two papers by Dr Guthe and Mr Rosa respectively deal with a new determination of the E M F of the Weston and Clark cells by a Gray electrodynamometer The construction of the instrument and the measurement of its exact dimensions are described in great detail by Dr Guthe in the first paper, while in the second Mr Rosa gives the complete theory of the dynamometer employed and discusses the effects of various errors, such as inaccuracy in the measurement of the dimensions of the coils, irregularities in their winding, and the effect of the opening in the fixed coil through which the suspension of the movable coil passes The chief results of the work are as follows —

The E M F of Guthe's "reference standard " cadmium cell, No 813, at 21° C = 1 01884 volts, or only two parts in 100,000 higher than the value given in its Reichsanstalt certificate The electrochemical equivalent of silver, determined by Guthe in 1904 (Bull Bur Stand , vol I part 1) in terms of a Weston cell, becomes, when recalculated to absolute measure, 1 11773 mg per coulomb, when the porous-pot form of coulometer is used

In the next paper Prof J G Coffin discusses the construction and calculation of inductance standards for Clark University and for the Bureau of Standards The paper gives in great detail an account of the successive operations One of the most interesting of these is the use for the accurate grinding of the marble cylinders of an especially fine grinding-machine on a novel principle, which will grind if required true cylinders up to 71 cm diameter, more than 3 metres long, and up to ten tons in weight The construction and winding of the cylinders presented many of the same problems as the making of the coils of the electrodynamometer referred to above, the coils in both cases being formed of a single layer of wire divided into several parts highly insulated from one another Following the practical details comes a long mathematical discussion setting forth the methods employed for calculation to the high accuracy required of the inductances of the various parts the two different formulæ employed giving, for the calculated self-inductance of one of the sections of the Clark University coil, values only differing by one part in four hundred thousand

The last paper by Messrs Hyde and Brooks, is on an efficiency meter for electric incandescent lamps It consists of an attachment to a photometer on which a scale of watts-per-candle can be arranged so that the "efficiency" of the lamp to be tested can be directly read off in a very simple manner without calculation The essential feature consists in the right design to give the desired result of a rheostat in the lamp-circuit, operated by the sliding of one of the photometer carriages A table of results shows that for a nominal sixteen candle-power lamp over a range of from ten to twenty candles with accompanying variation of watts per-candle of from 4 8 to 2 4, the value for the efficiency as obtained by the instrument and that determined independently by check instruments agreed everywhere to less than 1 per cent The value of the arrangement lies in the extreme rapidity with which a definite criterion for a large number of specimen lamps can be obtained without troublesome arithmetic

In part ii of vol II the first paper, by Mr Rosa, deals with the calculation of the inductance of single-layer coils The different types of " summation " and " current sheet " formulæ due to Rayleigh, Coffin, and Lorenz, and their suitability for use with coils of different shapes, are discussed at length Examples are also given showing the degree of concordance obtained in definite cases Tables of general application are calculated, from which the correction term for coils of varying number of turns, made of wire of different diameters, may readily be obtained

The paper by Mr H C Dickinson is entitled " Heat Treatment of High-temperature Mercurial Thermometers " It begins by recapitulating the methods of construction of high-range thermometers and the properties and suitability for different ranges of the various high-temperature glasses employed Tables of the departure of the natural scale of 16^{III} and 59^{III} glasses from the gas scale are given up to temperatures of 300° C and 500° C respectively The author then describes his own experiments, which deal chiefly with the effect of initial heat treatment on various unannealed thermometers of the different glasses specially constructed for research purposes The best methods of annealing such thermometers for rendering them as permanent as possible in after use are described An electric furnace arranged for the purpose is also shown The following are the more important conclusions of the paper —

(1) Jena 59^{III} borosilicate is the best thermometric glass in use for high temperatures, but it cannot be safely used much above 500° C

(2) Jena 16^{III} glass can be used up to 450° C

(3) Every thermometer intended for use above 100° C should undergo a suitable system of annealing before use The annealing may be done before the thermometer is filled A thorough anneal requires four to ten days at 450° C The anneal may be followed with advantage by a period of slow cooling of from three to six days

(4) To prevent the boiling of the mercury in a thermometer, the space above it should be filled with dry nitrogen or carbon dioxide having a pressure of one atmosphere at 300° C , of four and a half atmospheres at 450° C , and of twenty atmospheres at 550° C

Mr Brooks in his paper describes a new potentiometer for E M F and current measurements of intermediate accuracy It is primarily intended for use in such work as photometry, where rapidity of reading is essential, and where the best deflection instruments give an accuracy, insufficient in most cases

The feature of the new design is that the potentiometer method is used to balance the bulk of the electrical quantity to be measured, the remainder perhaps 1 per cent of the whole being shown by a suitable deflection instrument The design of a successful deflection potentiometer presents several difficulties In the present case these have been surmounted in a manner similar to that adopted by Stansfield, who was the first to use this type of instrument The greatest scale error in the new instrument described is 0 02 in 100 volts

In a paper on spectrum lines as light sources Mr Bates discusses the structure of the sodium D lines and the green mercury line $\lambda = 546 1$ $\mu\mu$ as sources in polariscopic measurements Sodium lines obtained in different ways show slight differences For intense illumination the author prefers sticks of pure Na_2CO_3 fed into an oxy hydrogen flame An echelon spectroscope was used for the study of the lines The position and intensity of the satellites of the green mercury line were accurately measured The use of this line is proposed as the standard source for all accurate polariscopic work A quartz rotation for wave-length 589 25 $\mu\mu$ may be obtained by measuring the rotation for the wave-length 546 1 $\mu\mu$, and multiplying it by the constant 0 850944

The paper by Mr Nutting, on polarimetric sensibility and accuracy hardly permits of useful abstraction It deals with the intensity and homogeneity of sources used in polarimetry The mathematical theory of the half-shadow polarimeter is discussed and formulæ given for calculating the sensibility of the instrument under varying

conditions A later paper by the same author describes a pocket spectrophotometer embodying some novel features

In the paper on the platinum-point electrolytic detector for electrical waves Mr Austin describes the so-called "barretter" patented by Fessenden, and used by him as detector in wireless telegraphy experiments It consists of a cell with electrodes, one a fine platinum point, the second a plate, the vessel being filled with an electrolyte giving gaseous decomposition products When an E M F is applied to such a cell polarisation ensues so that scarcely any current passes unless the E M F exceeds a certain critical value When electric oscillations pass through the cell the resistance is decreased, and the current for the moment increases Conflicting statements have been made by various investigators regarding the behaviour of the instrument, and the author has therefore subjected it to a thorough investigation, employing both ordinary alternating current waves and also the Hertzian waves from the station of the National Electric Signalling Company The chief conclusions of the research are —

(1) For the stronger alternating currents used the breaking down in resistance is approximately proportional to the square of the alternating current

(2) Under favourable conditions and with moderate polarisation the detector is equally sensitive to alternating currents with the point electrode, anode, or kathode

(3) The resistance of the detector for slowly alternating currents varied from 20,000 ohms to 400 ohms, according to the polarising E M F employed

(4) For electrical waves from a distance the detector is approximately equally sensitive with the point electrode, anode or kathode but for waves from a coil in the laboratory some cause appears to annul the sensitiveness of the kathode-point electrode

The next paper by Prof Coffin is a mathematical investigation on the influence of frequency on self-inductance, and is not capable of useful abstraction

Messrs Guthe and Austin then deal with experiments on the magnetic alloys discovered accidentally by Dr Heusler, and previously investigated at the Reichsanstalt and by Messrs Fleming and Hadfield Curves of permeability and inductance were determined for seven different samples the chemical analysis of which is also given An ingenious apparatus of high sensitiveness, quite cheap and easy to construct was designed for study of the magnetic expansion of the alloys This was capable of detecting changes in length as small as 5×10^{-7} mm The investigation is not complete but the relations between the curves of magnetisation and magnetostriction and between magnetostriction and thermoelectric force are clearly shown

The number and variety of the subjects dealt with in these two instalments of the official publication of the Bureau show that though only established three years ago it has already begun to make substantial additions to our knowledge of physics

J A HARKER

RESEARCHES IN STELLAR PARALLAX[1]

SOME years ago Dr Chase, of the Yale University Observatory communicated to the Astronomical and Astrophysical Society of America the results of a survey which he had carried out in collaboration with Dr Elkin in order to detect stellar parallax The number of stars examined was ninety two and these were generally selected from a list of stars having an annual proper motion of more than half a second of arc Of these ninety-two stars, fifteen had a negative parallax and, presuming that some of the smaller positive values were equally untrustworthy, some sixty were left which exhibited a real parallax amounting to more than 0″ 05 The scheme was one that seemed worthy of further prosecution, since the method employed proved adequate for the purpose of recognising the existence of measurable parallax Consequently, this work has been very considerably extended, and the recent publication from Yale gives the details of the discussion of no less than 163 stars, forming a contribution of the highest importance in parallactic inquiry Some thirteen years have been devoted to the completion of this work, in which, though Dr Elkin and Mr Smith have taken part, the heat and burden of the day has been borne by Dr Chase This will be seen from the following tabular statement, which shows both the class of stars examined and the distribution of the work among the several observers —

	Chase	Chase Elkin	Smith	Smith Elkin	Elkin
Stars with proper motion over 0″ 4	117	5	13	12	10
Stars selected by De Ball on account of magnitude	11	—	1	1	—
β Cygni, Algol, Nova Persei	5	—	—	—	—
Red stars for colour effect	6	—	—	—	—
Total number of series	139	5	14	13	10

The inquiry has been based entirely on measures of distance made with the heliometer As a rule, two comparison stars were selected on opposite sides of the star the distance of which was to be investigated, and in the direction of maximum displacement by parallax These comparison stars were as nearly as possible equidistant from the principal star When the arrangement of the stars did not permit this programme to be carried out completely special artifices had to be adopted On the other hand, in the case of stars of particular interest, a larger number of comparison stars was selected The precautions which Dr Elkin found necessary in the course of his work on the parallaxes of stars of the first magnitude were applied here, and further reference to these details is unnecessary Finally, the observations, when collected usually give for each star twelve complete observations, consisting of four groups of three nights each, taken at those seasons of the year when the parallactic displacement was at its maximum

A suspicion having been aroused that the measures of distance between two stars of different colours might need an additional correction for refraction a series of observations was made on some strongly coloured red stars taken from Kruger's "*Catalog der farbigen Sterne*" A term was introduced into the differential refraction correction of the form $\Delta\beta \tan z \cos(p-q)$ where p is the position, q the parallactic angle, z the zenith distance and $\Delta\beta$ the colour effect sought The several values of $\Delta\beta$ are as follows —

Star	Colour Scale	Δβ	Weight
Kruger 985	6 0	−0″ 019±0″ 019	63 6
,, 1080	7 0	+0 005±0 020	64 4
,, 1078	7 1	+0 009±0 015	16 0
,, 1181	7 8	+0 014±0 018	55 7
,, 1108	8 7	+0 046±0 017	45 2
W B XV, 745	—	0 003±0 021	55 6

The authors contend from these figures that the mean light of the red star is apparently refracted less than that of the comparison stars Whether this conclusion is justified or not, the quantities involved are so small that it can be safely asserted that there is no noticeable vitiation in the parallax results arising from this cause within the probable errors The remark attributed to Sir David Gill, that the tendency of the heliometer observer is to bring the similarly coloured parts of the star's spectra into coincidence rather than the brightest parts, seems to gain additional support from this investigation

Of the 163 stars examined the parallaxes range from −0″ 13 to +0″ 20, and the number of negative parallaxes is thirty-six Considering how wide the net has been spread to catch any star the proximity of which might be suspected on various grounds, the chance of finding stars closer to us than those which have already been examined grows very slight The scheme of the stellar universe so far as the few stars nearest to us are concerned, is taking fairly definite shape, and the scale that has been adopted from measured parallax will probably need no material alteration Such a conclusion is the more warranted, because the precision attaching to the mean value of a group of results is far greater than that of any individual determination The authors insist upon this point, and,

[1] "Parallax Investigations on 163 Stars mainly of large Proper Motion By Frederick L Chase, Mason F Smith and William L. Elkin Transactions of the Astronomical Observatory of Yale University, vol ii part i Pp 207 (New Haven The Observatory, 1906)

as a matter of fact, have grouped their results in various ways, all instructive. The average values obtained from these groups are of unquestionable significance

Seeing that the working catalogue was made to depend upon the amount of proper motion, it was most natural to arrange the final parallaxes in such a way as to show what relation existed between these quantities The following table makes this clear —

Range of Proper Motion	No. of Stars	Average Magnitude	Average Proper Motion	Average Parallax
" "			"	"
0 0 to 0 34	21	3 8	0 14	+0 019
0 41 to 0 54	39	6 3	0 49	+0 032
0 55 to 0 65	45	6 7	0 59	+0 059
0 66 to 0 96	46	6 5	0 77	+0 039
1 01 to 2 34	22	6 2	1 50	+0 109

Notwithstanding the drop corresponding to a mean proper motion of 0" 77, a distinct connection between parallax and proper motion is manifested. This relation is the more marked when the proper motion exceeds one second In these cases there is a uniformly positive and generally appreciable value of the parallax

The connection between parallax and magnitude is not so marked, though fairly evident It is however, to be noticed that the average proper motion has progressed tolerably uniformly with the magnitude, and this progression tends to mask any effect due to magnitude alone

Range of Magnitude	No of Stars	Average Magnitude	Average Proper Motion	Average Parallax
0 0 to 1 5	10	0 8	0" 61	+0" 095
2 0 to 4 9	29	3 8	0 53	+0 066
5 0 to 6 2	33	5 6	0 63	+0 056
6 3 to 7 0	34	6 7	0 73	+0 045
7 1 to 7 9	31	7 6	0 68	+0 017
8 0 to 9 0	36	8 3	0 80	+0 047

Other tables show the results arranged according to parallax, in order of right ascension, and according to the spectral type and classes as given in the Draper Catalogue From the last table we may quote the following —

—	Type I All Stars	Type I Rejecting Doubtful Spectra	Type II All Stars	Type II Rejecting Doubtful Spectra
Magnitude	4 0	3 5	5 3	5 4
Proper Motion	0" 42	0" 42	0" 67	0" 70
Parallax	+0 065	+0 066	+0 058	+0 056
No of Stars	13	11	81	69

The exclusion of the stars with doubtful spectra affects very slightly the mean values for each type, and the authors remark that although the evidence to be drawn from Type I is not very strong, it scarcely supports the law deduced by Kapteyn of larger parallaxes for Type II

The authors are to be congratulated on having accomplished a valuable long-continued series of observations, admirably planned and carried to a successful conclusion

W E P

RUSSIAN SCIENTIFIC PUBLICATIONS

THE work of the great N M Prjevalsky the first explorer of Central Asia, has been continued by one of his pupils and lieutenants Mr P K Kosloff, whose portrait appears as frontispiece to vol I of the account of the expedition conducted by himself in 1899–1901 to Mongolia and Cham This volume is dedicated to the memory of the great pioneer, who projected a fifth journey which he did not live to accomplish As a member of former expeditions, Mr Kosloff was well equipped for the vast undertaking which he describes At the end of 1898 he submitted a plan for exploration of the southern or Mongolian Altai, the neighbouring central Gobi, and if practicable, of eastern and central Tibet The Imperial Russian Geographical Society and the Ministry of War warmly approved, invested Mr Kosloff with powers of command and discretion, and furnished the expedition with scientific instruments Under distinguished auspices the party made its way to the Altai station, and halted to survey the sublime snow-clad range and to collect specimens Here the members met with a venerable member of a company of Old Believers, Rachmanoff whose pilgrimages and adventures of more than forty years are mentioned by Prjevalsky Having achieved satisfactory results, the expedition moved into the arid, sandy wastes of Gobi, an unattractive region It met with a hearty welcome at the Tshortentan monastery from the lamas, whose personalities and the etiquette of their rule are described at length Next the party proceeded to the salt-marsh district of Tsaidam The Mongols of this region appear to have had a distinguished history, but in course of time were forced to cede territory to Chinese and Tibetans, their conquerors compelling them to destroy all documents and records of the earlier Mongol princes There is only local tradition to depend upon, without any means of verification A chapter is devoted to an ethnographical sketch of the Tsaidam Mongols, and in other chapters the author discusses Mongolian marriage customs and folklore A wallet of excellent maps, showing the routes taken by Prjevalsky and other explorers, is appended to the volume

An interesting account of exploration and observations in an uninviting region is given in Dr W N Tuchoff's volume on the western shores of Kamchatka In the preface, Mr K Bogdanovitch explains that the author, a medical student at Dorpat, had a strong desire to investigate the geographical conditions of Kamtchatka and spent ten years there almost without interruption No one but an ardent naturalist would be attracted to this vast area of volcanic ridges and tundra, of monotonous aspect The main interest lies in the descriptions of the life and occupations of the Kamtchadals, who are exposed to a hard struggle with nature and are suspicious of foreigners Dr Tuchoff relies chiefly upon diaries and data collected between 1896 and 1898, and on reports of the Amur section of the Imperial Russian Geographical Society Each chapter is devoted to the conditions of a particular district

Although fish is the staple food of the inhabitants and their dogs, the fishers do not exercise much judgment, and lament that catches are consequently less numerous The people are exceedingly simple and childish, as Dr Tuchoff shows by humorous stories, and Russian officials of routine temperament sometimes fail to understand them He devotes some space to their superstitions, *e g* the story of the brethren man and bear, and the divinity driven through the woods in a sledge drawn by partridges "The bear population of Kamtchatka," he quaintly observes "predominates over the human, and there are more chances of meeting a bear on the road and in the woods than a man," but with more numerous visits of hunters the bears retreat into the more inaccessible regions In one district mothers quiet refractory children by threatening them with the Russians in the same way as Border parents used the name of the "Black Douglas" Illumination of the poor dwellings is effected by means of bear or seal fat in a primitive kind of lamp, with moss or a piece of rag for a wick, the results being dismal light, much soot and foul air Dr Tuchoff urges the necessity for a series of meteorological observations with a view to the agricultural prospects, and indicates sites for stations Cattle-breeding a feature of settled life, is more developed where there is a Russian settlement, and the author's opinion is that the Kamtchadal native is in the transition state from nomad to settled habits and that he wants practical instruction in rearing of stock It is unfortunate that the natives degenerate when in proximity to the Russians The concluding chapter is devoted to the language, which varies in north and south, and appears to be dialectical Dr Tuchoff confesses himself unable to reproduce all the sounds of words, partly because European alphabetical resources are inadequate and partly because the ear can only distinguish some with difficulty The transliteration of lists of words in Russian and Latin characters is perplexing to the eye There is an excellent index and map at the end

Mr. N. M. Knipowitsch has compiled a volume of more than 1500 pages, embodying the results of much research, under the title of "Bases of the Hydrology of the European Ice-ocean" (i.e. Barents and the White Seas). The author proposes to give a full and exact picture of the physical geography of the ice-ocean, so far as that is possible at the present time, to record some deductions with regard to biology and geology, and to construct a firm groundwork for future investigations. He modestly leaves his conclusions open for future proof, but none the less must be congratulated on the accomplishment of this work, which will unquestionably be of great value to students of marine conditions. Accordingly Mr. Knipowitsch reviews previous literature, gives lists of temperature at many points, tables indicating degrees of saltness, differences of temperature according to depths, analyses of sea-water, its clearness and colour, with chapters on hydrology, biology, and geology, a series of about sixty practical deductions, and appendices. A short abstract in German appears at the end. The author refers to other works of his own, to Scandinavian authorities, *e.g.* Nansen and Pettersson, and to men of a former generation, as Scoresby, and the Siberian explorer Middendorf.

Vol. xxviii. of the Transactions of the Novo-Rossisk Society of Naturalists of Odessa, shows that the labours of a relatively small body have produced very important results. The work opens with an appreciation of the late president, Prof. R. A. Prendel. Botanists will delight in the exhaustive examinations during two summers by Mr. I. Okinshevitch of the forests of northern Bessarabia, which he says, "in spite of the rich and abundant nature of this country, is very little known from the natural history point of view." The Pliocene and post-Pliocene deposits in south Bessarabia are the subject of a study by Mr. Grigorovitch-Berezovsky. Mr. M. S. Pantchenko describes the hydrological work of the late Admiral S. O. Makaroff; it was he who finally settled disputed points with regard to the navigation of the Bosphorus, after careful survey, the cruise of the *Vitiaz* round the world resulted in the collection of comparative data from different seas; but Makaroff is perhaps best generally known as the designer of the ice-breaker *Yermak*. His untimely death deprived Russia of one of her greatest practical men of science. Mr. A. Brauner writes extensively on the reptiles and amphibia in several provinces. The volume concludes with the report of the society for 1904.

The Tungus race of Siberia has been studied by Mr. S. Patkanoff, who devotes a volume to the Tunguses proper and another to the Manzhurs, Daures, Solones and other tribes. The Russians first came into contact with the Siberian aborigines early in the seventeenth century, while the Cossacks were extending the conquests initiated by the famous Yermak in the reign of Ivan the Terrible. The Tunguses formerly occupied a large territory, but were driven northwards by the incursions of Buriats, Yakuts, and other Asiatics, as well as of Russians. The Cossacks observed that a certain amount of culture was known to the Tunguses, who wore iron helmets, shields and chain-mail in battle. The principal occupations of these people are breeding of deer, hunting, and fishing. The pure type is now difficult to trace owing to admixture with other races for some considerable period. Travellers have paid high tribute to their many excellent qualities in comparison with other Asiatics, especially as regards honesty. Middendorf found strong mountaineering characteristics among the Tunguses, probably survivals of an earlier period. Kastren styled them "the noblemen among Siberian tribes." Various tribes are dealt with as carefully by the same author in the second volume, which also contains notes on the languages and dialects with specimens, a map of Siberia illustrating the distribution of Tungus tribes, and another showing their position in the Amur region. This work evinces the thoroughness with which the Russians are studying and mastering the varying conditions and populations of the vast territories owning the Tsar as sovereign.

Messrs. B. M. Zhitkov and S. A. Buturlin have compiled an interesting volume of materials for the ornithology of the Simbirsk government, though they do not claim that it is exhaustive, and have not covered all the ground. The groups dealt with comprise Pygopodes, Longipennes, Limicolæ, Alectorides, Gallinæ, Columbæ, Lamellirostres, Herodiones and Rapaces. The area is largely broad, cleared steppe country, with a fauna such as might be expected in a corn-growing region. Oases of forest or grass land, with abundance of water at intervals, intersect the monotonous plains, and shelter corresponding forms of animal life. The authors have spent fifteen years in observation and collection of materials.

In a report on a geological investigation extending from Mukden to Liao-yang, shortly before the Russo-Japanese war, Mr. Y. S. Edelstein, a Russian explorer, writes:—"Many people consider Manchuria a country of extraordinary richness in minerals. This fame does not rest on sufficient evidence, as in the first place the question of quantities and qualities of useful minerals in Manchuria is still too little known, and in the next, even in the present condition of our knowledge of Manchuria, it is scarcely possible to doubt that many areas of Siberia, the Urals, and Europe surpass it in this respect." Auriferous sand, thanks to barbarous and primitive methods of working, loses the major part of its value in the eyes of a European contractor, and the extensive employment of modern machinery is the only way to secure advantage from working.

In his account of a botanical expedition in Ossetia and Colchis (Transactions of the Imperial Russian Geographical Society, vol. xxxviii., No. 3), Mr. V. V. Markovitch writes that the beech of the Ossetian forests, considered by botanists as being identical with the species *Fagus silvatica*, L., of western Europe, was discovered by Lipsky to be a new species and styled by him *Fagus orientalis*, Lipsky. Lipsky based his conclusions largely upon differences in fruit. Mr. Markovitch finds that the lignine of the Caucasian beech does not resemble that of *Fagus silvatica*. The German name *Rotbuche* is due to the colouring of the lignine after hewing, which does not occur in that of the Caucasian variety, which remains white.

THE BRUSSELS SOCIOLOGICAL SOCIETY.[1]

THERE are at the present day many earnest students of sociology. It is only natural, therefore, that we should find societies for the investigation of sociological questions springing up. The publications of the Instituts Solvay for 1906 are already fairly bulky, though as yet we have the output for the first half of the year only. There are seven "fascicules," the largest of which contains three hundred pages. One, possibly two, of the papers contained in them, though not to a great extent original, may be described as distinctly able. The aim of the first paper (by E. Solvay) is to prove that sociology must be founded on biology. Of course, if the nature of a society is to be investigated, it is well as a preliminary to learn all that is to be known about the individuals of which it is composed. It is well to make this clear at the outset, but it may be doubted whether anything is gained by arguing this out elaborately and mathematically.

The second paper (by E. Waxweiler) sketches the methods of sociology. A young science must, of course, try to be ultra-scientific. It is sure to be decried as an upstart that has no right to claim admission to the pantheon of the sciences. It is bound to insist that there shall be no vagueness of terminology, and that words shall be accurately used. Our author is quite right to emphasise the importance of such matters. When he goes on to deal with evolution, we find much with which we cannot agree. The struggle for existence he seems to count almost as a myth, and he would substitute for it the idea of "an irresistible tendency towards life." Such big, vague assumptions are far more unscientific than the casual methods which our author condemns. So at least it seems to the present writer. A little further on we find living organisms divided into three classes—"vegetables, animals and men."

The third paper (by R. Petrucci) is, like the second, a long one. It deals with the natural origin of property. The author is no doubt right when he maintains that, independently of legislation, there may be property and

[1] "Instituts Solway—Travaux de l'Institut de Sociologie." Parts 1–5 and 7. (Bruxelles and Leipzig: Misch and Thron, 1906.)

ownership When he goes on to assert that plants have property, that a plant "possesses a definite territory," he seems to be playing with words In the organ-pipe coral he finds an example of collective ownership, the individual polype also having something in the way of private property In animals of a higher class, e g in ants, the notion of property does undoubtedly show itself This paper is illustrated, and some of the pictures are excellent, but a picture of the nest of *Formica rufa* does not help us to understand the subject of property

The fourth paper (by L Wodon) is brief, and deals trenchantly with some sociological theories, notably with those of Karl Büchner, who maintains that primitive man was a non social being This creature of theory lived in lands where the abundance of natural products made any large output of energy on his part quite unnecessary Our author satisfactorily disposes of this primitive lotus-eater

Dr E Houzé has contributed a distinctly able paper (fascicule No 5) on the Aryan and anthroposociology He has a thorough grasp of his subject, his style is clear, and he has a fine sense of humour The wonderful theories of the comparative philologist he sends to the limbo to which such theories must sooner or later find their way He goes rather too far when he maintains that the Aryans were the creatures of the philologists It is true, no doubt, as he argues, that no race has ever maintained its purity for any length of time unless it happened to be geographically secluded The pure bred Aryan stock that we were taught to picture to ourselves ranging over great part of Asia and all of Europe is a myth But it is difficult to believe that the people who spoke the Aryan tongue in different parts of the world had not a fairly strong strain of kindred blood in them, though they intermarried freely with the tribes and peoples among whom they found themselves Still far too much has been made of the Aryans as a separate type, and Dr Houzé is right to laugh at what has been called "Anglo-Saxon pandolichocephalism" a term invented to describe "the skull which has the honour of sheltering the brain that has guided the world" M de Lapouge the champion of the "dolichocephalic blond Aryan" is very severely dealt with Dr Houzé is a strong believer in natural selection He keeps quite clear of the untenable view that it goes on in the organic world generally whereas among men it has somehow become a thing of the past "When the sun has baked the grass," he remarks "it forces innumerable troops of antelopes to migrate is not this the same cause that drives the Germans to embark at Hamburg for America? It is a question of food" Archæology he holds supplies the firmest foundation for anthropology, and he speaks with great respect of such men as de Morgan Arthur Evans, and Flinders Petrie Anthropometry he puts in its proper place Nothing can be more absurd as he says, than to make size of skull alone an absolute measure of brain capacity When he discusses existing populations and their characteristics Dr Houzé shows great soundness of judgment As to the question of town and country life he holds that the commonly held opinion that towns "devour their inhabitants with rapidity" is at any rate an exaggeration On the modernism of Teutonic civilisation he makes some very sensible remarks The Teutons appeared late on the stage of history and it was only their contact with Gallo-Roman civilisation that enabled them to reduce their legends to writing

The last of the papers we are reviewing (by R Petrucci) takes pains to prove that animal associations were developed independently of one another They do not form a series culminating in human communities In tracing the descent of birds and of men from simpler forms of life, the author shows a thorough understanding of the subject About animal societies he has much interesting information—about the sociability of reptiles about the form the family takes among fish birds, and mammals Apparently he does not point out (a curious omission) the interesting fact that the pairing instinct is strong only in those species in which the energy of both parents is required for the feeding or protection of the young We regret that we have not space to deal more fully with this last paper Those who are interested in animal associations would do well to study it

IS THERE DETERMINATE VARIATION?

IN an article published in *Science* of November 16, Prof Vernon L Kellogg, of Stanford University, discusses the question as to the existence among organisms of determinate variation, that is to say variation in the same or a similar direction in a large number of individuals of a single species If such a factor does exist one of the objections to the origin of species by natural selection—namely, that small individual variations would be eliminated in a generation or two—disappears

Prof Kellogg's observations refer to variation occurring in the Californian flower-beetle, *Diabrotica soror*, inhabiting the Stanford University "campus" Large series of this chrysomelid beetle, varying from 500 to 1500 in number, were collected on that area in the years 1895, 1901, 1902, 1904, and 1905 Normally, the beetle shows six dark spots arranged in pairs on each wing-cover Individuals show, however, a tendency to the transverse coalescence of the two middle or two lower spots on one or both elytra, or a longitudinal fusion of the three spots on each half of the elytron In 1895 the majority of the beetles had twelve free spots on the two elytra, but among the variations there was a marked tendency to the transverse union of the two middle spots, either on one or both elytra, the percentage being 22 40 In the years 1901–5 a much larger percentage of this variation occurred, reaching 53 92 per cent in one series in 1905 and 65 40 per cent in 1904

After adducing arguments to show that the variation is neither ontogenetic (that is, determined for each generation during development by external influences) nor the result of natural selection Prof Kellogg falls back on determinate variation "If" however he writes, "determinate variation is the explanation of this change in *Diabrotica soror* it is a determinate variation which is occurring only apparently, in our particular locality For in series of specimens of this beetle collected in other parts of California no such change seems to be going on the old twelve spots-free form being plainly the modal type Why the species should be changing on our university campus and not changing in the regions south and north of us is a mystery whose solution I do not even dare to guess it This solution must have to do with the cause of the variation of the species on our campus But if one asks what is this cause, what it is that is producing determinate variation in Diabrotica or in any other species it must be mentioned that prior to any attempt to explain how determinate variation might be produced it is advisable to attempt to determine if determinate variation really exists Is there determinate variation?"

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

LORD CURZON OF KEDLESTON, who was appointed to be the Romanes lecturer at Oxford for 1906, but was prevented from delivering the lecture, has been appointed the Romanes lecturer for this year

MR WILLIAM SMITH of Geneva, has says *Science*, given 100 000*l* to Hobart College to endow a college for women It is also announced that Dr Andrew Carnegie has offered to give 20 000*l* to Queen's University, Ontario, on condition that an additional sum of 80,000*l* be collected

MR J D ROCKEFELLER has made a New Year's gift to Chicago University of about 600 000*l*, which brings his total benefactions to the University up to 3 900,000*l* The private gifts to universities and colleges in the United States announced in these columns during last year amounted to nearly 5 000,000*l*

THE annual meeting of the Public School Science Masters' Association will be held at the University of London on Saturday, January 12 The president the Rev the Hon E Lyttelton, headmaster of Eton, will take the chair, and will read a paper on the place of science and of literature in a general education Other subjects of papers upon which it is hoped discussion will take place are —"The Internal Economy of School Science" by Mr Thwaites, and "The Best Method of Introducing the Atomic Theory in Science" by Mr F R L Wilson

In connection with the University of London, we notice that Mr A G Tansley, assistant professor of botany and lecturer on plant anatomy at University college, will deliver a course of eight lectures on "The Evolution of the Vascular System in the Fern-phylum," beginning on January 26, at University College At the physiological laboratory of the University a course of eight lectures on "The Physiological Effect of Compressed Air" will be given by Mr Leonard Hill, F R S, beginning on January 15 A course of five lectures on the "Structure and Classification of the Myriapoda and Arachnida" will be given at University College by Mr R I Pocock, beginning on January 14

The Paris correspondent of the *Times* reports that M Briand, the French Minister of Education, proposes to suppress the baccalauréat, the degree conferred on a boy on his admission to a French university Such admission is of necessity preceded by several years' school training during which the boy is prepared in a somewhat mechanical manner for the examinations on which his admission to the university depends The system, according to the *Times* correspondent "is the nearest approach known in Europe to the mandarin method of China" It is very widely felt that at the end of their school careers the boys lack initiative and originality as the result of the undue appeal to their verbal memories, and it is hoped that the abolition of the baccalauréat will discourage the rigid uniformity which characterises French secondary schools and lead to an endeavour to adapt the curriculum of a school to the particular needs of the pupils attending it

Several substantial gifts for the advancement of higher education are recorded in recent issues of *Science* Among these may be mentioned donations of 20,000*l* each to Western Reserve University, Cleveland, O by Mr H M Hanna and Colonel Oliver H Payne The 40 000*l* thus subscribed is to be used in establishing and endowing a laboratory of experimental medicine in the medical school Mr William Smith of Geneva N Y is to found a woman's college The name of the new college will be the William Smith College for Women, and it will have an endowment of about 70 000*l* A "Carl Schurz memorial professorship" is to be established at the University of Wisconsin as a result of the movement recently started in Milwaukee by a number of prominent German Americans The plan is to raise an endowment of 10,000*l* the income of which will be used for the establishment of an annual course of lectures at the State university to be given by prominent professors of German universities Mr Andrew Carnegie has offered to give Washburn College, Topeka Kans a second 10 000*l* for its endowment fund, provided the total endowment reaches 40 000*l* by January 1, 1908

The tenth of the series of articles on "Public School Education" which is being published in the *Times* appeared on December 28, 1906 This contribution deals with laboratories and practical work in the teaching of science and is by the Rev T Nicklin, of Rossall School Mr Nicklin says "it would be hard to find a single public school of recognised position that has not a laboratory which if not palatial is yet adequately equipped for that end of science teaching that is regarded in England as educationally best" A little later the article asserts that while the masters in the public schools adhere to the theory that lectures and intellectual teaching must be the staple of the work, the English public schools have from the first made considerable use of the laboratory, and to-day that use is on a larger scale and more thorough in character than ever before Mr Nicklin describes the laboratories of an average public school, and indicates briefly the course of study followed Though it would have been more satisfactory if in addition to his generous estimate of Prof Armstrong's work in improving English science teaching Mr Nicklin had insisted more upon the paramount importance of laboratory practice in the teaching of science, his article is valuable in showing the very substantial improvement made during recent years in the way in which science is regarded by public-school authorities Many readers of NATURE will remember the days when any sort of practical lesson was unknown in public schools and to hear that every such school now has well-equipped laboratories—even if in some cases they are not used enough—is convincing proof that the labours of men of science in the direction of rationalising English public-school education have not been in vain.

SOCIETIES AND ACADEMIES

LONDON

Zoological Society, December 11, 1906 —Dr H Woodward, F R S, vice-president, in the chair —An account of the ascidians of the Cape Verde marine fauna collected by Mr Cyril Crossland Dr J **Rennie** and H **Wiseman.** The occurrence of ten species of Ascidiæ Simplices was recorded, of which three were described as new —Variations in the arterial system of certain species of Anura L K **Crawshay.** —Descriptions of fifty-three new species of African Coleoptera of the family Curculionidæ Guy A K **Marshall.** —The cranial and spinal nerves of *Chlamydoselachus anguineus* Mrs O A Merritt **Hawkes** The paper contained a description of these nerves and discussions of them from the point of view of the nerve-component theory, and showed that the nervous as well as the other systems of Chlamydoselachus combined specialised and primitive features —Two mammals obtained by Major Powell-Cotton in the Ituri Forest R **Lydekker** The author referred a dark-coloured cat's skin to a race of *Felis chrysothrix* and also described a giant elephant-shrew as new —The skull of a bruang, or Malay bear, from Tibet representing a distinct race R **Lydekker** —South Indian nudibranchs Sir Charles **Eliot.** A supplementary account of the radulæ of various species based on microscopic slides prepared by Alder and Hancock, discovered in the Hancock Museum at Newcastle-on Tyne These slides confirmed many of the identifications suggested in the first paper, and in particular showed that *Doris glenei* was a Chromodoris, and that *Doris villosa* was *Thordisa maculigera*, Bgh

Faraday Society, December 11, 1906 —Dr T M Lowry in the chair —Contributions to the study of strong electrolytes Dr A C C **Cumming** (1) *The Elimination of Potential due to Liquid Contact* —Certain solutions have the property of reducing the potential due to the contact of two solutions and potassium chloride has been used for this purpose In most cases a saturated solution of potassium chloride does not remove all the diffusion potential indeed if the solutions in the cells be strong, it only removes a small part This property of removing more or less of the diffusion potential depends on two factors in the connecting solution first, the positive and negative ions must be of equal velocity, and, secondly, the concentration of the connecting solution must be high compared with the solutions in the cells The author suggests a saturated ammonium nitrate solution as that which fulfils these two conditions better than anything else at present known, and shows by experiments with different cells that this is the case (2) *The Potentials of Silver Nitrate Solutions* —For silver nitrate the electromotive force gives the same measure of the ionic concentrations as is obtained from the conductivities, and therefore supports the view that the conductivity gives a true measure of the ionic concentration —The electrochemistry of lead Dr A C C **Cumming.** The results in general prove that lead in the tetrad form is a highly electropositive element, and also direct attention to a curious difference in the behaviour of sodium and potassium nitrates towards lead nitrate —Storage batteries and their electrolytes R W **Vicarey.** The paper deals chiefly with some of the problems involved in the manufacture of accumulators particularly as regards the effect of nitrogen and other impurities introduced consciously or by accident in the process of manufacture

PARIS

Academy of Sciences, December 24, 1906 —M H Poincaré in the chair —The determination of integrals of equations of the elliptic type by certain conditions at the limits Émile **Picard.**—Differential equations of the second order at fixed critical points Paul **Painlevé.**—Magnetic work at the town of Tananarivo and district Ed El-

Colin. A table is given showing the results of the magnetic observations at twenty stations, to which is appended a discussion of the perturbations.—The evolution of the Tertiary mammals: the importance of migrations. The Miocene epoch: Charles **Depéret.**—The perpetual secretary announced the death of Jean Abraham Chrétien Oudemans, correspondant of the academy for the section of geography and navigation, and of Jacques Augustin Normand, correspondant for the same section.—The nature of the atmospheres of Mercury and Venus: P. **Salet.** Details are given of the method of observation by which it has been found that the light from Mercury is not sensibly polarised. It was shown by Landerer in 1892 that the light from Venus is similarly not polarised. The author concludes that it would be premature to draw conclusions as to the nature of the atmosphere of Mercury from this result.—A formula applicable to the times of direct rotation of the planets and the sun: Émile **Belot.** The formula proposed is

$$T = \frac{23.75}{\sqrt{a}\, D^{\frac{1}{17}}} + \frac{0.61D}{\sqrt{d}},$$

where T is expressed in hours, a is the distance from the centre of the system, D the diameter of the planet in diameters of the earth, and d the density with respect to water. The times are calculated from this formula in ten cases and the causes of the two large deviations observed, the sun and moon, discussed.—A method in the calculus of variations: M. **Hadamard.**—Partial differential equations of the second order with two independent variables admitting a group of odd order of transformations of contact: J. **Clairin.**—The extinction of friction: L. **Lecornu.** The motion is considered of a system of homogeneous spheres having their centres fixed, and which exercise given mutual pressures at their points of contact. It is shown that this system, once set in motion and left to itself, has the peculiar property that the work of friction, with respect to the unit of time, tends constantly to diminish. This theorem still holds when, for one or more of the points of contact, the sliding is replaced by a rolling.—The unsymmetrical modification of some absorption bands of a crystal under the action of a magnetic field: Jean **Becquerel.**—The variation of ferromagnetism with temperature: Pierre **Weiss.** A theory of ferromagnetism is given based on a simple hypothesis concerning the mutual actions of the molecules. Experiments have been carried out on magnetite, which previous experiments had shown to be sensibly saturated in a field of 500 Gauss, and of which the temperature corresponding to the disappearance of magnetism, 587° C., is easily accessible. The curve drawn from the theory is given, and on the same diagram ten experimental points are shown. The correspondence is very close at one temperature only, that of solid carbonic acid, there being a sensible deviation from the curve.—The negative charge at a distance of a metallic plate illuminated in an electric field: Mme. **Baudeuf.**—The cryoscopy of colloidal solutions of ferric chloride: G. **Malfitano** and L. **Michel.** The authors have shown the possibility in previous papers of using a collodion filter to separate the fine particles from the liquid in which they are suspended, and in the present paper apply this method to determine the lowering of the freezing point of the latter, considered apart from the small particles. In this way they find that the cryoscopic effect of the suspended particles is so small as to be beyond experimental measurement. In this case, at any rate, the magnitude of the suspended particles cannot be determined by cryoscopic methods.—The absolute atomic weight of dysprosium: Gustave D. **Hinrichs.** A discussion of the experimental results of G. Urbain. The atomic weight of dysprosium is assumed to be 162.5 exactly, the experimental figures and those based on this assumption are compared, and the deviations noted.—A colloidal compound of thorium with uranium: Béla **Szilard.** The compound described is obtained by heating precipitated thorium hydrate with solutions of uranium salts.—The action of alkaline silicates on soluble metallic salts: Robert **Dollfus.** A description of the phenomena observed when a crystal of ferrous sulphate is thrown into a solution of sodium or potassium silicate. The experiment has some analogies with the culture of the artificial cell described by Traube and by Stéphane Leduc.—The definite compounds formed by chromium and boron: Binet **du Jassonneix.** The ingots obtained by reducing chromium oxide by boron in the electric furnace contain two compounds, Cr_3B_2 and CrB, both of which dissolve in a medium containing less boron, and which can only be isolated in a state of purity from nearly homogeneous ingots, the composition of which nearly corresponds to the substance required.—The anhydrous protoxides of the alkaline metals: E. **Rengade.** By applying to rubidium, potassium and sodium the method previously used to obtain the oxide of cæsium, Cs_2O, the lower oxides of these metals, possessing the general formula R_2O, have been obtained in a pure state.—Some sulphates of tetravalent vanadium: Gustave **Gain.**—The use of special steels for rivets: G. **Charpy.** A systematic study of the thermal and mechanical properties of various alloys of steel has led to the use of a chrome nickel steel for rivets, the strength of which is 2.5 times that of the metal usually employed for this purpose, and this without the need of any special precautions in practical use.—Some methods of estimating nitriles and carbamines: H. **Guillemard.**—A new method for estimating free sulphur: E. **Berger.** The sulphur is dissolved by fuming nitric acid to which a little potassium bromide has been added. This reagent acts in the cold, and in a few minutes.—The molecular weight of elaterine: A. **Berg.** The author has repeated his determinations of the molecular weight of elaterine, with the result of confirming his earlier views. The formula would appear to be $C_{28}H_{38}O_7$.—Contribution to the study of the hydroxamic acids: R. **Marquis.** Benzhydroxamic acid treated with thionyl chloride, gives phenyl isocyanate by a kind of Beckmann transformation. Salicylhydroxamic acid behaves differently, oxycarbanil being quantitatively formed.—A new method of formation of organic compounds of phosphorus: J. **Berthaud.** White phosphorus, heated with an alcohol in a sealed tube at 250° C., after some hours completely disappears. Among the products of the reaction are phosphines, hydrogen phosphide, some phosphinic acids, and tetralkylphosphonium hydrate, the latter being the chief product.—The experimental reproduction of lithospherical folding: M. **Hirtz.** The effects of the gradual contraction of a planet are imitated by a layer of paraffin enclosed between two distended rubber spheres, the internal one being slowly deflated, and the contact of the external sphere with the paraffin being maintained by external pressure. The surfaces thus produced are compared with the surface of the moon.—The origin of helicoidal windings in crystallised bodies: Fred. **Wallerant.**—Corrosion figures: P. **Gaubert.** A study of the corrosion figures produced on phthalic acid crystals by mixtures of alcohol and water.—A new mineral species, nepouite, a hydrated silicate of nickel and manganese: F. **Glasser.** The mineral was found in New Caledonia. The analyses lead to the composition $2SiO_2.3(Ni,Mg)O.2H_2O$. INDIAN CLIMATOLOGY.

Climatological Atlas of India Published by the Authority of the Government of India, under the Direction of Sir John Eliot, K C I E, F R S Pp xxxii + 120 plates (Issued by the Indian Meteorological Department, 1906) Price 36s

THE Indian network of meteorological observations is the greatest individual organisation within the tropics, and it has, therefore, attained the greatest importance in the pursuit of meteorology and climatology Founded in the year 1875, it can now look back upon more than thirty years of uninterruptedly successful activity, having during this period had the peculiarly good fortune to be presided over by two distinguished meteorologists—Henry F Blanford and Sir John Eliot From the commencement the author of this review has followed with sympathetic interest the development and the active work of the organisation, has been in constant association with its director, and has also, as far as possible, made use of the immense volume of information In no meteorological organisation in the world are there such comprehensive records, as well of a statistical as of a scientific nature, as in the Indian one, only the much older Russian one can compare with it Beginning with the smaller, but very valuable, scientific essays of Blanford in the Proceedings of the Asiatic Society of Bengal, it grew into the huge folio volumes of the Indian Meteorological Memoirs, of which the seventeenth volume is completed and published Then came monographs relating to individual cyclones, Blanford's "Indian Meteorologist's *Vade Mecum*" (Calcutta, 1877), and especially the five volumes of cyclone memoirs by Sir John Eliot, and his "Handbook of Cyclonic Storms in the Bay of Bengal" (second edition Calcutta, 1900)

The introductory text to the "Climatological Atlas" gives a summary of the publications of the Meteorological Department, relates the history of the development of the department, and describes its objects and aims Reference may here be permitted, to an older publication, "Memoirs of the Indian Surveys," by Sir Clements R Markham, K C B, F R S (second edition, London, 1878 xvi, pp 275–310), in which is minutely described the beginnings of meteorological efforts in India, down to the establishment under Blanford of a single organisation, it also gives a very good analysis of the meteorological work until the year 1875 The text of the "Atlas" contains the most important facts as to the principles on which the construction of the charts is based, the means are critically derived from the observations of the twenty-five years 1876–1900 [1]

The Indian network of meteorological observations extends from about latitude 6° N, in the tropical Indian Ocean, to the prodigious plateaus of the Himalayas, under 35° N It includes, in the south as well as in the north, hill stations at and above 6000 feet above sea-level, which supply information on the upper strata of the atmosphere The region contains the hottest and the most rainy parts of the world, and it is the scene of one of the most peculiar meteorological phenomena—the south-west monsoon—in which the wind *régimes* of the two hemispheres meet between 30° S and about 30° N

From the accumulated meteorological records in this highly interesting region we have now this splendid chartographic production, the "Climatological Atlas of India" This work excels in its completeness even the similar work the "Atlas Climatologique de l'Empire de Russie" (St Petersburg, 1900) In a certain sense these two great works are complementary to each other, giving us such a very extensive picture of the climatic variations over the largest continental area of the world—Asia and Europe—as one would hardly have hoped for a short time ago The "Indian Climatological Atlas" contains a very valuable peculiarity—it takes into consideration the *daily* variation of the meteorological elements, explaining their extension over the country during the extreme day hours 8 a m (10 a m for pressure) and 4 p m, and also the daily variations of pressure and temperature In India these daily variations play a most important part The smaller charts complete in a clear manner the information on the large charts, and they are of very great practical value

The "Atlas" contains 120 charts in perfect technical finish, as is expected from Bartholomew's Geographical Institute The first chart (double) exhibits in a very excellent manner the orographical features of the Indian Empire the knowledge of which is very important for the understanding of the progress of meteorological phenomena over them Another two page chart shows the political divisions of India, influencing the selection of the meteorological stations Then come four smaller maps, showing the rainfall divisions according to Blanford and Eliot respectively the medical provinces, and the meteorological divisions for the Daily Weather Report Upon these introductory representations follow a couple of double-page maps showing the distribution of the pressure and the winds in the opposite months January and July These charts embrace the whole of India and the East African and Australian monsoon regions, extending from 35° S to nearly 50° N, from Asia Minor and East Africa in the west to Japan and the greater part of Australia in the east With these we are in a position to see at a glance the distribution of pressure with the north-east and with the south-west monsoons Both charts are very instructive, and particularly the July one, for it shows the origin and advance of the south-west monsoon of western India, which Sir John Eliot first completely explained A uniform decrease of pressure prevails then from the south Indian Ocean, under 30° S up to the foot of the Himalayas, in 30° N, with a difference of pressure of close upon an inch (30 3 inches in the south and 29 4 inches in the Punjab) The wind systems of

[1] The complete numerical values are found in various volumes of the Indian Meteorological Memoirs

M

the southern and northern hemispheres unite, and there is no longer a division at the equator This is the great summer monsoon of southern Asia, which in the whole world has nothing to compare with it

In this, as in succeeding pressure charts, it is seen that in many places the winds recorded are in opposition to the distribution of pressure (local disturbances?) In the January chart we miss the north-west monsoon over the Malay Archipelago (it is found over North Australia), although at Batavia, for example, west, north-west, and north winds prevail in January with a frequency of more than 80 per cent, and similarly also prevail in strength

Plates xi-xxiii exhibit the distribution of mean pressure and the winds for each month and the year at 8 a m, the hour of observation for the telegrams for the Daily Weather Report Besides these there are two smaller charts showing the pressure and wind at 10 a m and also at 4 p m, that is, at the hours of the daily extremes In the quiet, cool-weather season the winds experienced undergo changes of direction in accordance with the distribution of pressure In the Ganges valley, in May, at 4 p m, they appear to blow against the gradient, that is, from the lower to the higher pressure, the problem of the nor'-westers, which had already occupied the attention of Blanford

Plates xxiv-xxxvi show the mean pressure and the winds for the day, the smaller charts the actual diurnal range of pressure, and the range reduced to sea-level, monthly and annual From January to May, in southern India, the daily range of pressure is as much as 0 15 inch to 0 17 inch, during and after the rainy season it diminishes to 0 13 inch or 0 12 inch These great daily amplitudes justify the representation of the mean daily distribution of pressure In Plates xi-xxxvi the monthly and annual isobars are drawn at intervals of 0 05 inch, an interval which would be ample for Europe, but for a tropical region it appears to be too large The pressure gradient which sets the great south-west monsoon in motion does not amount to so much as 0 02 inch per degree We see, therefore, upon some charts—February, March, October, and November—only two to four isobars over the whole of the extensive region, and sometimes it is not very clear as to the local decrease of pressure, especially over the Bay towards the east This could have been easily remedied by specially noting the mean pressure at the Nicobars, Andamans, and on the coast of Burma

As to the origin of the most interesting phenomenon in the meteorology of India—the bursting of the monsoon—the charts which lie before us cannot afford sufficient explanation, for the origin lies outside the limits of the charts, far southward in the Indian Ocean, not over the Indian land region, as Sir John Eliot pointed out (Quarterly Journal of the Royal Meteorological Society, January, 1896) The gradual advance of the southern and western sea breezes in the mighty south-west monsoon we see in the charts for February and March to June The south-west monsoon reaches Ceylon about the middle of May, and arrives at Bombay about the middle of June So gradual does the advance seem from April to May and from May to June that it is scarcely noticeable in the charts, but we do, however, find an indication. On the May and June charts we see a higher pressure advancing from south and south-west, while in northern India pressure is decreasing A pressure wave spreads over India from May to June This is clearly shown in the following pressure changes from month to month —

		Changes from		
		April-May In	May-June	June-July
Zanzibar ..	6 12 S	+0 066	+0 009	+0 019
Colombo	6 54 N	−0 014	+0 009	+0 016
Trivandrum .	8 30 N	−0 007	+0 003	+0 009
Mooltan	30 12 N	−0 149	−0 147	−0 019
Dera Ismail Khan	32 0 N	−0 145	−0 161	−0 013

From May to June southern India is flooded with masses of air from the ocean by the south-west monsoon, while over north-west India pressure continues to give way

Plates xxxvii-xlix contain the monthly and annual mean temperatures over India, the isotherms being drawn for differences of 0° 5 F, and are, therefore, of an especial distinctness The smaller charts give the lines of equal mean monthly and annual maximum and minimum temperatures The succeeding plates, l-lxii, are also devoted to temperature, the large ones showing the lines of equal diurnal range, the small ones the lines of equal absolute maximum and minimum values, monthly and annual The whole of these plates, therefore, afford a very complete picture of the temperature of India From the isothermal charts we can easily follow the warming of the Indian land area from south to north-west In February the warm centre, 82° 5, lies under 16° N (mean), in March, 87° 5, under about 17° N (the middle of the peninsula), in April, 92° 5, under 21° N, in May the centre, 95°, embraces the whole of western India, reaching from 18° to 27° N In June it takes up a position towards the north-west, in the Punjab—the Mooltan region—with 97° 5, one of the highest monthly temperatures in the world In July the cooling sets in, 95°, and in August it is 90°, whilst on the Malabar coast, under the influence of the rains, the temperature is already down to 77° (in 12° to 16° N) In the northern Punjab, where the heat centre lay in June, the temperature sinks to 55° (down to 52° 5) in January There also are to be found the absolute extremes of the whole of India 125° in June and 30° to 25° in January The daily range of temperature varies between 10° on the southern coasts and 32° 5 in the north-west The rainy season brings to the whole country a great decrease of the daily range of temperature, from 30° and 32° 5 to 15° in Central India

Plates lxiii-lxxv show the distribution, monthly and annual, of the mean daily relative humidity, the two smaller charts on each sheet the distribution at 8 a m and 4 p m In the Central Provinces in April the atmospheric humidity decreases to 30 per cent in the daily means, and to 20 per cent at 4 p m, whilst on the coast it is 70 per cent, and in Upper

Assam 80 per cent On the west coast during the rainy season it is 90 per cent, in the Punjab 50 per cent to 60 per cent In similar manner Plates lxxvi–lxxxviii, show the mean distribution of aqueous vapour, monthly and annual, and at 8 a m and 4 p m, the changes are mostly the reverse of those of relative humidity The mean vapour pressure reaches 0.90 inch to 0.95 inch on the coasts and over the Bay of Bengal in May, while in January it is only 0.40 inch over the land The rainy season brings to the whole peninsula a high vapour pressure, but on account of the decrease of temperature it is generally not higher than 0.85 inch, only in the lower and middle Ganges valley is it 0.95 inch The daily variations of the relative as well as of the absolute humidity are very great in the dry season

The charts exhibiting the distribution of humidity are followed by Plates lxxxix–ci, showing the mean daily cloud distribution Here also we find smaller charts representing the cloudiness at 8 a m and 4 p m Such an exhaustive picture of cloudiness as we have presented to us in these Indian charts did not hitherto exist for any part of the world The difference in the cloudiness in various parts of India in the several seasons is very great In the middle Indus valley we find a mean cloudiness of 1.5, in Upper Assam of 6.0—these are the extremes in the annual means In June the Punjab has still only 1.0, the Malabar coast and Assam 8.0, in western Bengal even 9.0 In October the minimum, 0.5, lies in the Punjab, the maximum, 8.0, in southern Deccan The technical finish of these maps is especially beautiful and impressive

We now come to the concluding series, Plates cii–cxx, representing the rainfall conditions The principal charts, monthly and annual, show the rainfall distribution by means of isohyets, the smaller ones give the lines of equal mean number of rainy days and the storm tracks for 1876–1901 Until now no monthly rainfall charts for India had been in existence H Blanford had added to his great work on the rainfall of India ("Memoirs," vol iii) merely an annual chart The principal areas of rainfall in India—the Malabar coast and the Khasi Hills of Assam, with from 200 inches to 450 inches of rain annually—are generally well known, but what we regard as the most extensive rain region is the Malabar coast rather than the Khasi Hills, as is especially evident from the June and July charts On the Malabar coast in July we find a long area with 50 inches of rain, whereas the Khasi Hills have only the isohyet of 20 inches (Cherrapunjee omitted) In June both regions have isohyets of 30 inches The driest region is in the lower Indus valley (round the hottest place in India—Jacobabad), with an annual total of only 5 inches The mean values of the number of rainy days lie between the limits of 10 on the lower Indus, 125 on the Malabar coast (Cochin) and in Assam, and 200 in the south-west part of Ceylon The isohyets are also drawn for the seasons—for January and February, March to May, June to October, and November and December (the main annual Indian seasons), and also for the combined results for December to April and for May to November The smaller charts show the number of rainy days, and for January, May, July, and October the midday isobars at an elevation of 10,000 feet On the chart for January and February appear the welcome rains of northern, and especially north-western, India, shown by isohyets of from 2 inches to 5 inches, on the March to May chart the spring rains in Assam, from 20 inches to 30 inches, and on the west coast of Ceylon, 20 inches, are particularly noticeable

Of special interest are fifteen smaller charts giving the storm and cyclone tracks (period 1876–1901) In the winter half of the year, the cool season, we find the storm tracks (paths of the depressions) in north India, mostly north of 24° N First, in November there are two, in December thirteen storms in the direction from the lower Indus towards the Ganges delta In January there are more than thirty northward of 24° N, while there are only four southward to 20° N In February they still remain in northern latitudes, we see two main paths with twenty-five tracks—in March not more than twelve This seems to be the end of the period of winter storms in north India On the April chart we already find the tracks of four great cyclones over the Bay of Bengal, the Arabian Sea and from the latter two advancing towards north-western India To the cyclone tracks are attached the dates, so that the direction and velocity can be ascertained, but with the storm tracks we miss an indication of the direction of movement of the depressions (say by means of an arrow) We certainly know that in the winter half-year in northern India these tracks are generally directed from west to east, but as we proceed through the year there are doubtful cases, as the summer depressions from the Bay up to the Ganges valley and westward towards Central India In May, and again in October and November, we find numerous tracks over the Bay, in November also over the Arabian Sea In this month two cyclones crossed the peninsula, and, therefore, the Ghats, from the Bay to the Arabian Sea (between 12° and 14° N)—rare cases In December only one great cyclone moved up the Bay from south to north, and some smaller ones from east to west During the rainy season (June to September) the upper north-west corner of the Bay becomes the birthplace of numerous depressions, which pass into the country In September this "area of cyclonic storm generation" extends further south to 15° N, and also goes further into the Bay These are the storms which carry the rains of the Ganges valley upwards and over Central India During the months of June to August it appears that even on the land depressions are developed which go westward (direction of movement wanting) as far as the Indus Three small charts show these land-formed storm tracks (period 1886–1900)

We now conclude our cursory examination of the very richly-stored volume of charts lying before us, for which science as well as practice, so long as they have to depend upon climatic factors, are indebted to the Indian Government Sir John Eliot, the author of this work, has produced a worthy monu-

ment of himself as the director of the Meteorological Service of India. We now look forward with the greatest interest to the promised "Manual of Indian Climatology," which, as an addition to the "Atlas," and especially in the interest of the general public, is indispensable. Our knowledge of the meteorology of India has now extended so far beyond the region of the instructive and concise work of Henry F. Blanford, "Climate and Weather of India" (London, 1889), that a new description on a broader foundation appears to us an absolute necessity.

J. HANN.

A NEW TREATISE ON EVOLUTION

Einführung in die Descendenztheorie. Sechs Vorträge. By Prof. Karl Camillo Schneider. Pp. viii+147. (Jena: Gustav Fischer, 1906.) Price 4 marks.

THIS is a book with many good points. It gives a fairly complete account of current opinion on the subject of evolution, including the most recent views concerning the nature of variation and the laws of inheritance. Most of the facts cited are sufficiently familiar, but they are explained with unusual lucidity and conciseness. Where authorities differ, their conclusions are as a rule impartially stated, and when, as often happens, the author's own judgment is at fault, he will generally be found to have supplied his readers with material for forming a sounder opinion. The illustrations are copious and well-selected, and the book as a whole will serve as an adequate introduction to modern evolutionary theory.

So far as argument goes, the most effective part of the work is its criticism of Lamarckism, from which, however, we miss any mention of Prof. Ray Lankester's convincing demonstration of the self-contradictory nature of Lamarck's "laws." The author appears to attach far too much importance to the "mutations" of de Vries, and regards as well-established certain conclusions on this head which recent researches have seriously shaken. His objections to the part assigned to selection by Darwin and his followers are singularly feeble, and we are not surprised to find that his knowledge of many of the most important facts bearing on this branch of the subject is imperfect. His account of mimicry, for instance, is quite out of date, and the vast mass of highly significant material that has been accumulated under the influence of Fritz Muller's theory of common warning colours is almost entirely ignored. An error, or rather a series of errors, which unfortunately found their way into Weismann's latest work (as pointed out in NATURE, vol. lxxii., 1905, p. 201), reappears in the coloured plate appended to the present treatise. As these errors remain uncorrected in the English translation of Weismann, and have since been copied into several other publications in Germany and America, it may be well to direct attention to them here in detail.

In the plate referred to (Taf. II.), Fig. 1 represents, not, as stated, the male of *Papilio merope*, but the female of the north-east African form, *P. antinorii*. Figs. 3 and 4 are not "forms of *P. merope* from South Africa," Fig. 3 being the *hippocoon* form of the female of *P. tibullus*, a race of *P. dardanus* which occurs in East Africa from Mombasa to Delagoa Bay, and Fig. 4 representing the female of *P. echerioides*, a species quite distinct from the *dardanus* or *merope* group. The butterfly represented in Fig. 6 is not, as stated, *Amauris niavius* from South Africa (the form usually called *dominicanus*), but belongs to the West African race of the species. Finally, in Fig. 7 is shown, not the Danaine *Amauris echeria*, "the immune model of Fig. 4," but another Papilio, viz. the *cenea* form of *P. dardanus* ♀, the mimic having been here mistaken for its model. These mistakes are the less excusable in that several of the forms in question have been carefully discussed and figured by Prof. Poulton.

The great difficulty to be faced by those who, like the author of the present treatise, seek to minimise the influence of selection, is the universal prevalence of adaptation. We accordingly turned with some interest to the passages in which he gives his own solution of the problem. We must confess to a feeling of disappointment. The author makes no serious effort to grapple with the question; he appears to be satisfied with vague phrases about "extra-personal correlation" which explain nothing, while his dictum—emphasised by spaced type—"Artbildung ist einerseits Vervollkommnung, andererseits Anpassung," when taken with its context, seems to savour of the heresy of orthogenesis. However, he claims for his book that it is only an introduction, not an attempt at explanation, and in both parts of the claim we think he is justified.

F. A. D.

OUR COAL RESOURCES

The Coal Question. By the late W. Stanley Jevons. Edited by A. W. Flux. Third edition. Pp. l+467. (London: Macmillan and Co., Ltd., 1906.) Price 10s. net.

THE first edition of Jevons's lucid and exhaustive work was published in 1865 and the second in 1866, and since that date it has constantly been referred to, but almost always misunderstood. The Royal Commissions of 1866 and 1901 both shared the general misunderstanding. This is certainly surprising in view of the care the author took to make his position clear. He argued that within a century the want of coal would seriously check our material progress if the rate of progress in consumption shown at the time at which he wrote were maintained.

Since Jevons's tragic death in 1882 (NATURE, vol. xxvi., p. 420), no one has pointed out the superiority of his logical method over that of his many critics. It is, therefore, a matter for congratulation that Prof. Flux, of McGill University, who was formerly Stanley Jevons professor in the Owens College, Manchester, has edited a third edition, in which he has wisely preserved the text unaltered so far as might conveniently be done, while making such additions as were necessary to embody the knowledge accumulated in the forty years since its original issue. The most important change in the general situation since then is the development of the coal resources of Germany

In regard to this and other developments, the editor has obtained much help from the reports of the Royal Commission on Coal Supplies, and particularly from Mr Bennett H Brough's report on foreign and colonial coal resources to that Commission This material is ably and attractively dealt with by the editor, who shows that it is probable that the exhaustion of the British deposits will not progress much, if at all, more rapidly in relation to their total contents than will be the case with the German coal, and that the reported coal resources of Canada and Australia suggest the reflection that even though an increasing cost of power in Great Britain involve the decay here of the industries on which our country's preponderance is based, the industrial greatness of the British Empire may not pass away

The first chapter forms practically the author's preface to the first edition, and the subsequent chapters in the new edition deal with the following subjects —opinions of previous writers, the geological aspect of the coal question, the cost of coal mining, the price of coal, British invention, the economy of fuel, supposed substitutes for coal, the natural law of social growth, the growth and migrations of our population, the change and progress of our industry, our consumption of coal, the export and import of coal, the comparative coal resources of different countries, the iron trade, problem of the trading bodies, taxes and the national debt, and concluding reflections The width of economic and erudite information and the patriotic tone of the original work have been well maintained, and the whole has been admirably brought up to date The only trifling matter that has escaped the editor's notice is that in a few cases the titles of some of the authorities cited which changed in the course of time have not been altered Thus, Lord Armstrong appears as Sir William Armstrong, Sir Henry Bessemer as Mr Bessemer, Sir Andrew Ramsay as Prof Ramsay, and Lord Swansea (Sir Henry Hussey Vivian) as Mr Vivian The able editing and the arrangement of the matter, as well as the attractive form in which the book is produced, cannot fail to commend themselves to all who share John Stuart Mill's admiration of the work and of its author

THE RELIGION OF THE MALAYS

The Peninsular Malays I Malay Beliefs By R J Wilkinson Pp 81 (London Luzac and Co, 1906) Price 2s net

VARIOUS classes of students, in addition to the Civil Service cadets for whom it is primarily intended, should read the most excellent pamphlet on "Malay Beliefs" recently written by Mr R J Wilkinson The author is one of the most erudite of students of the Malay language, classical and dialectical, and he has acquired an intimate and sympathetic knowledge of Malay customs and beliefs This little book contains a clear statement of the strange mixture of Mohammedan creeds and practices that obtains in the peninsula As Malay Islamism was mainly introduced from southern India, the Malays are Sunnites like the Moslems of the Deccan, but owing to the predominance of Persian influence in India Shiite "heresies" have crept in, further, in the matter of religious law the Malays are Shafeites Below and penetrating through this imported religion are aboriginal vestiges of paganism, always strongly tinted with magic

Mr Wilkinson has some interesting remarks upon the problem of the relation of magic to religion that is at present exercising the minds of students of comparative religion He says —

"The magician may 'indicate' some person to receive the special attention of spirits of disease, much as a man sets his dogs upon an enemy Sometimes by the use of a waxen or other image, or by the exhibition of a 'sample' such as the parings of a man's nails or the clippings of his hair, the wizard conveys to the world of ghosts a knowledge of the person he wishes them to attack- and the ghosts are ever ready to profit by the hint so kindly given Here the practices of Malay witchcraft come very close to sympathetic Magic—to the view that there is 'a certain physical sympathy between a person and his image'

'It is not wax that I am melting
But the liver, heart and spleen of So-and So'

"Nevertheless there is a marked difference between the animistic magic of the Malays and the 'sympathetic magic' defined in Frazer's 'Golden Bough' and accepted by Mr Skeat as the explanation of the use of waxen images in the Peninsula The following invocation (quoted by Mr Skeat himself) shows the real nature of the practice

'Salutation to thee Oh Prophet! Ruler of the World!
Lo! I am burying the corpse of So-and-So
Do you assist in killing him or making him sick'

"The actions of the sorcerer merely illustrate or indicate to the spirits the exact nature of the service that he expects of them If these performances were really based on a belief in 'a certain physical sympathy between the person and his image' it would be unnecessary to invoke the spirits at all"

Mr Wilkinson gives some good examples of accurate observation but inaccurate inference from the facts Thus people have noticed that man-eating tigers have the great canine teeth almost entirely worn away, and they infer that the loss of the teeth is a punishment for man-eating, and not that the beast is driven by the loss of his weapons to the desperately dangerous expedient of preying upon man Again, they know that venomous snakes have stumpy tails, and assume that the use of the venom causes the tail to drop off The author also gives a suggestive account of the training and methods of the native doctor who has some real knowledge of drugs, diet, fomentations and massage, and a thorough knowledge of the weakness of human nature His dodges perplex or mislead rival practitioners, while they delight his patients with the special attention that he appears to be devoting to their individual needs

It is to be hoped that the author will redeem his promise of issuing other pamphlets on Malay literature, life and customs, government and law, history, and industries

OUR BOOK SHELF

John Dalton By J P Millington Pp xii+225 (London J M Dent and Co, 1906) Price 2s 6d net

THIS volume constitutes the latest addition to the series of "English Men of Science" now in course of publication by Messrs J M Dent and Co, and is a concise and well-written account of the illustrious author of the atomic theory Everything there is to tell about the old Quaker philosopher has already been told in such well-known works as the "Memoirs" of Henry and of Angus Smith, and in the lesser-known biography of Dr Lonsdale, and all that a modern historian can do is to put together, with such literary skill as he can command, the facts of his simple, uneventful life The publication of the "New View of Dalton's Atomic Theory" by Sir Henry Roscoe and Dr Harden, and the criticism which the "New View" has received from Debus, might have afforded an opportunity to Mr Millington for the exercise of his critical acumen, but Mr Millington fails to avail himself of it, the quotation from the "Fundamental Satze der Chemie," published two years before the appearance of the "New View," having little relevance to the matter in dispute between them

Mr Millington's narrative is simple and unaffected in style, befitting the character it seeks to describe It is calculated to give the reader a just and faithful impression of a calm and beautiful life, utterly unworldly, and free from any taint of self-seeking, envy, or greed

It might at first sight be thought there was no room for another book on Dalton, but we cannot have too much of such an example, and certainly no biographical series of "English Men of Science" would be complete which omitted his great and honoured name

Verhandlungen der deutschen zoologischen Gesellschaft, 1906 (Leipzig W Engelmann, 1906) Price 10 marks

THIS volume contains the papers read at the sixteenth annual congress of the society held at Marburg, June 5-7 1906 The number of subjects covered by the papers and "demonstrations" is so great that it is only possible to refer to a few On account of being fully illustrated, special mention must be made of a communication by Prof L Plate on the evolution of species in the Bahama land-shells of the pupa group classed under the title of *Cerion glans* The gradation from a large-sized, heavily-ribbed, and uniformly coloured type to a diminutive one in which the place of ribs is taken by bands of colour is admirably illustrated in the plate

In the second paper illustrated by a plate, Dr F Doflein deals with the fauna and oceanography of the Japanese coast, especially from the point of view of the dispersal of organisms in his opinion continental barriers offer much less serious obstacles to the dispersal of marine organisms than is commonly supposed The zoological distribution of animals also forms the subject of a paper by Dr E Stromer, who discusses the bearing of the recent discoveries of fossil vertebrates in the Tertiaries of Egypt on current theories as to the origin of the modern African fauna

Considerable general interest likewise attaches to a long paper, by Prof Simroth on the fauna of Sardinia, which deals in considerable detail with the origin and relationships of the native breeds of domesticated animals, and brings out some noteworthy points in connection therewith Most of the other papers deal with subjects of interest only to specialists It may be added that methods of modern research form the subject of the opening address to the session by Prof Hertwig, and that at the inaugural meeting Prof Korschelt gave an historical sketch of the rise and progress of the zoological institute of the University of Marburg

Photograms of the Year 1906 Pp 164 (London: Dawbarn and Ward, Ltd, n d,) Price 2s

IN these pages we are introduced to a series of excellent reproductions of typical photographic pictures of the year This has been compiled by the editors and staff of the *Photogram*, and a descriptive article accompanies the series Mr A C R Carter contributes a criticism of the two great photographic exhibitions, namely, the "Salon" and "Royal"

In addition to the above, pictorial photography is dealt with in several other essays by various writers Thus Mr Roland Rood writes about America, Mr Mortimer Lamb about Canada, The year's photography in Spain is dealt with by M Mendez Leon, while "Western Workers in the United States" is the subject of an article by M Fayette I Clute

As this annual is noted chiefly for the reproduction of photographs, and in this issue the standard is excellent, it may be mentioned that the principal illustrations are reproduced by Messrs Carl Hentschel, Ltd, and the printing by Messrs F W S Clark and Co, Ltd, on the "first quality art" paper of Messrs John Dickinson and Co, Ltd

One of the frontispieces is an excellent three-colour picture reproduced and printed by Hentschel-colourtype from negatives by Mr William Gill To those photographers who are mainly concerned with the "pictorial" branch of photography this annual will therefore prove of great interest

Les Nombres positifs Exposé des Théories modernes de l'Arithmétique élémentaire By M Stuyvaert Pp xii+132 (Gand Van Goethem, 1906) Price 3 francs

THIS treatise certainly deserves a trial by school teachers The author realises that there is a great gulf between arithmetic, as usually taught in schools, and the strict logic of the subject, and, at the same time, that it is impossible to teach it with complete rigour to a school class He assumes the commutative law of addition, and then proves the elementary rules in a way which is quite sufficient for school purposes, and does not involve any fallacies which afterwards have to be renounced The treatment of irrationals follows Dedekind, that of fractions is based upon the definition that $a/b=c/d$ if $ad=bc$ Proportion is treated in the way that is usual in France, the section on this subject would require to be expanded and illustrated by the teacher, the same is true of other articles, notably § 13, which is unduly condensed, and where the distinction between algebraic and arithmetical divisibility is rather blurred Many teachers will regret seeing contracted multiplication expounded by Oughtred's rule of reversing the digits of the multiplier The rule for contracted division, though instructive, is needlessly complicated from a practical point of view, and, alas! the rule for arithmetical subtraction is given in its old-fashioned form However, these are minor points, and it is worth while to refer to them only because the book is so attractive in other respects Attention should be drawn to the author's way of considering fractions, which he sketches out in his preface

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Treatment of Cancer

IN NATURE of December 20, 1906, I note an article (pp 177–8) on "The Treatment of Cancer" As a scientific investigator, I must dispute the truth of the fact that I have any co-discoverer in this matter of the use of pancreatic ferments in the treatment of malignant growths As, of course, you are well aware, all priority in scientific discovery depends upon publication In the case of the medical man mentioned in the article there has never been any publication of scientific facts, and the reference to the comparative immunity of the small intestine from cancer has a very different scientific explanation from that given in the *British Medical Journal*, 1906, p 715 The real reason is the very small extent of the original piece of gut, out of which, by growth within itself, the mammalian small intestine is developed If the explanation given by this medical man were correct, the cœcum ought to be as immune from cancer as the lower end of the small intestine This gentleman has never claimed to have discovered *a* cure, let alone *the* cure, for cancer What he professes to have found is that the proteolytic ferment, trypsin, and not the diastatic one, amylopsin splits up glycogen This is a very remarkable find to have made! Assuming a miracle to have happened when these unpublished experiments were made, and that trypsin *did* split up glycogen, it may be asked why he and his pharmacist adopted for use as an injection into human patients, from about the end of February last until recently, a decoction containing a small amount of practically pure trypsin, which had no action whatever upon glycogen?

The medical man who made this remarkable find, which will not stand the test of confirmation, himself writes in the pages of the *Medical Press* of December 19, 1906, as follows —"Every medical man must deplore the frequent attempts which are made in the Lay Press to induce the public to believe that a cure for cancer has been discovered" This is clear enough Against it I, a scientific man, now affirm not only that *a* cure has been found, but that my own work and discoveries have revealed *the cure* For the evidences of the truth of this statement I will not refer to various microscopic preparations of tumours after treatment, removed by operation, at a *post mortem*, or sloughed away, for these are the property of physicians in England and America who will themselves publish their cases

Instead, as the space at disposal is limited, I will refer to Prof W J Morton's preliminary report in the New York *Medical Record*, December 8, 1906, to the other cases in course of publication there, and to the brief account of the Naples case of inoperable cancer of the tongue, which I hope to see published shortly in the pages of that medical journal Six months after all treatment ceased the patient is alive, well and free from cancer

This is the sequel of the use of preparations of pancreatic enzymes, scientifically prepared, and employed by such able and distinguished physicians as Cavaliere Guarracino and Prof Manzo The cancer yielded to the chemical test The reagent for this is not, as so many in this country have believed, including certain cancer researchers, a solution of glycerine and water, possibly containing a little trypsin, but it is a potent extract of pancreas-gland, prepared from the fresh gland direct, and containing *all* the enzymes

The writer of an article in the *British Medical Journal* for December 15, 1906, p 1736, who displays a close knowledge of the unpublished work of a research body, states that trypsin is among the substances condemned in the passage cited from the fourth annual report of the Imperial Cancer Research Fund I have not used the term "trypsin treatment," for I agree with Prof Poirier, of the French Cancer Research, that trypsin will destroy cancer, but not cure it The preparations used must be such as those manufactured by Messrs Fairchild Bros and Foster, and they must be employed in the way directed by a scientific investigator If the statement be aimed at the course of treatment advised by me, a scientific man, and, as a chemical trade newspaper says, "not even a medical man," if this be the case, I now direct the attention of the scientific members of the executive of the Imperial Cancer Research Fund to its existence I traverse it completely, and deny that it contains a vestige of truth As I have produced evidences of its falsity, if it refer to the pancreatic treatment, I now call upon these scientific men to substantiate the truth of the point by the production of evidences, including a clear account of the means adopted to obtain a proper injection compound, or to retract and withdraw the assertion, for what happened in Naples has also occurred in New York, as well as in other places in this country, even in the neighbourhood of this city of Edinburgh

J BEARD

8 Barnton Terrace, Edinburgh, December 23, 1906

WITH reference to the above letter questions of priority are not involved in the article referred to It may be that Dr Shaw-Mackenzie's advocacy of the trypsin treatment of cancer was based on a misconception, but that he did independently evolve it seems clear to us, and this is all that was suggested in the article His line of treatment is indicated in a letter to the *British Medical Journal*, May 27, 1905, p 1183, and again in the same journal, January 27, 1906 p 240, in the latter not only trypsin, but pancreatin and secretin are suggested As regards the term "trypsin treatment," Dr Beard, in an article in the *British Medical Journal* (January 20, 1906, p 140), uses the phrases, "the length of time and number of injections of trypsin necessary to destroy the tumour" "trypsin is the substance which will destroy the cancer cell (Beard and Shaw-Mackenzie)," &c , and he moreover states, "the preparation of trypsin employed (Fairchild Bros and Foster's) was that originally dispensed to Dr Shaw-Mackenzie's prescription by Mr F W Gamble," thus acknowledging Dr Shaw-Mackenzie's work, and actually making use of the latter's preparation of trypsin! Accepting the details of the case of cancer of the tongue cured by pancreatic extract as correct, it is a remarkable one, but not unique The writer knows a case of mammary cancer diagnosed as such 4½ years ago by four doctors, and on which a London surgeon refused to operate, which after treatment with X-rays has atrophied, and the patient is well and in good health to-day, surely as remarkable a case! Lastly with regard to the alleged cures of cancer obtained by Prof Morton in America (to which reference was made in the article), these are summarised in the *British Medical Journal*, December 22, 1906, p 1835 About thirty cases were treated, and the results claimed are cure in two cases, remarkable atrophy of the tumour in one, and arrest of disease in many In one case the "cure" has lasted four months, in the other one month! It is absurd yet to speak of such cases as "cured", careful surgeons allow a *three years'* limit! To claim that "the cure" for cancer has been found has at present nothing to substantiate it, and in our opinion Dr Shaw-Mackenzie's position is far more scientific than Dr Beard's We believe that the pancreatic enzymes must be injected into the neighbourhood of the growth or used locally, how, then, could the secondary growths in internal organs &c , be attacked? Until this can be done, no "cure" for cancer will have been obtained

THE WRITER OF THE ARTICLE

The American Gooseberry mildew

I GIVE below the facts concerning the outbreak in England of this disease

This mildew, *Sphaerotheca mors-uvae* (Schwein), Berk —known in America since 1834—has proved so destructive there as practically to prevent the cultivation of the European gooseberry on a commercial scale [1] It was unrecorded in Europe until 1900 when it appeared in a few gardens in the north-east of Ireland It has spread over

1 See, for example, Year Book U S Dept Agric , 1899 also Bull 114 161, N Y Agric Exper Stat

the eastern half of Ireland, causing great damage.[1] The disease has broken out on the Continent, and assumed epidemic proportions, causing such devastation that drastic legislative measures are being employed. The evidence shows that the outbreaks have originated from gooseberry-plants imported from America.[2]

In October last I discovered the disease in an English nursery on standard gooseberries recently imported from the Continent, and later in commercial plantations in one of the chief gooseberry-growing districts of England. I have since been warning fruit growers, by means of lectures and otherwise, of the new danger. I have taken every step to impress on the Board of Agriculture the necessity for preventing further importation of diseased plants and for enforcing the destruction of all those already infected.

The Board, on being informed of the outbreaks, sent Mr. Massee to the infected districts. As the result of his visit, a series of statements throwing doubt on the foreign origin of the disease and its serious nature have been widely circulated in the Press. These, as coming from the mycologist to the Board of Agriculture, have caused many growers to relax, at this critical stage of the first outbreak, their efforts to stamp out the disease.

I am convinced that there is no scientific foundation for the statements referred to. I have suggested[3] that the points at issue should be submitted to arbitration, for it is most important to fruit growers that no doubt should be allowed to remain on a matter which so affects their interests.

The Board has issued a circular warning growers of the serious nature of the disease, but it does not recognise that the disease is new to the country, and that legislation is necessary. Unless the Board takes stronger measures at once, and unless the effect of the statements made by Mr. Massee can in some way be counteracted, nothing can prevent the disease from spreading and causing losses of many thousands of pounds. F. S. SALMON.

[MANUFACTURERS of filter presses are invited to put themselves into communication with our correspondent.—ED. NATURE.]

ARCHÆOLOGICAL DISCOVERIES IN TURKESTAN.

WE have referred already (NATURE, December 13, 1906, p. 155, and December 20, 1906, p. 180) to the archæological expeditions of Dr. M. A. Stein and Dr. von Lecoq in Central Asia. News of Dr. Stein's second expedition, which has resulted in further finds of importance, has lately been received, and details of the discoveries of Dr. von Lecoq (foolishly described in a telegram from India as comparable with those of Layard and Rawlinson!) have been communicated by the discoverer to the Srinagar correspondent of the *Times of India*, quoted in the *Times* of January 3. From these it is evident that Dr. von Lecoq's discoveries are, as might have been expected, analogous to those of his forerunner, Dr. Stein, in imitation and emulation of whose work the Prussian expedition of Dr. von Lecoq was sent out. The MSS. documents found by Dr. von Lecoq are, with the exceptions noted below, of the same type and in the same languages as those found by Dr. Stein, and, further, Buddhist paintings of the kind described by Dr. Lecoq as "the missing stepping-stone by which Indian art advanced across Asia to Japan" were first found by Dr. Stein.

This being said, however, we must note that Dr. von Lecoq's work was carried out in a different part of Turkestan from Dr. Stein's, in the vicinity of Turfan and Urumchi, as well as at Kucha and Kurla. It is therefore to be expected that the results of the Prussian expedition, while generally analogous to those of the Indian ones, will show peculiarities due to difference of geographical position, &c., and it may well be that Dr. von Lecoq has discovered objects of later date than any found by Dr. Stein. The documents which he has found are mostly of the same kind and in the same tongues as those found by Dr. Stein, but some are written in new, or rather little-known, languages, such as Tangut, Koh-Turki, Middle Persian written in the Manichæan alphabet, and a sort of Central Asian dialect of Syriac. Manuscripts in ordinary Syriac were found; these are, of course, monuments of the Christianising activity of the Nestorians in Central Asia from 600 A.D. to 1000 A.D. A curious discovery is thus described:—"The furious zeal of the Chinese conquerors of Turkestan against Buddhism was exemplified by the discovery of the packed bodies, still clad and odorous, of a multitude of Buddhist monks driven into a temple, and stifled there, more than a thousand years ago."

Dr. von Lecoq's colleague, Prof. Grunwedel, is still working in Turkestan. Already fifteen chests of MSS., and altogether about 200 cases of "finds," have been sent to Berlin. "The expedition up to date has cost the German Government 10,000*l.*, a sum which may be contrasted with the 800*l.* spent on Dr. Stein's epoch-marking expedition of 1900–1 by the Indian Government." Comment upon this fact is superfluous, and would in any case be useless.

The current number of the *Geographical Journal* contains a letter from Dr. Stein, dated from Keriya on October 10, 1906, giving an account of his work up to date. Apart from his trigonometrical surveys of the Kuen-lun mountains and his archæological re-examination of the Buddhist monument known as the Rawak Stupa (already mentioned in NATURE), Dr. Stein excavated a small ruined temple in "the extensive débris-strewn areas known collectively as the Tati of Hanguya." Here he found terra-cotta rilievos of the fifth to sixth century A.D., often covered with rich gilding. Dr. von Lecoq reports similar discoveries of gilt paintings. East of the Khotan oasis Dr. Stein excavated ruined shrines near the village-tract of Domoko, that of Khadalik yielded MSS. of the same date as those discovered by Dr. Stein previously at Dandan-Uiliq. In one were found stringed rolls of Chinese copper money, deposited by one of the last devotees before the storm of Tibetan conquest wrested the land from the Chinese. At the time of writing, Dr. Stein was proceeding from Keriya to the eastern sites beyond Niya.

AT THE BACK OF THE BLACK MAN'S MIND.[1]

THERE can be no question as to the originality and value of this book as a contribution to West African ethnology. Mr. Dennett has lived many years amongst the Bavili and other tribes of the Kakongo district (Luango coast) immediately north of the Congo mouth. He has also of late lived as an official several years in the Benin district of the Niger Delta. About three-quarters of the book under

[1] Journ. Roy. Hort. Soc., vols. xxv.–vii., xxix. (1900–6).
[2] See Eriksson, *Zeitschr. f. Pflanzenkrankh.* Bd. xvi., also work of de Jaczewski.
[3] The *Times*, December 28, 1906.

[1] "At the Back of the Black Man's Mind; or, Notes on the Kingly Office in West Africa." By R. E. Dennett. Pp. xv+288. (London: Macmillan and Co., Ltd., 1906.) Price 10s. net.

review deals with the hierarchy of kings and chiefs, the laws, social organisation, marriage, birth, and death customs, psychology and philosophy of the Bavili; the remainder of the book treats with much the same subjects as they have been observed by the author in Benin. Finally there is a valuable appendix by Bishop James Johnson on the religious beliefs and social laws of the Yoruba people.

To anyone interested in the Bantu languages or in the social organisation of the Bantu peoples Mr. Dennett's book will be of great importance. He reveals to us the existence of a relatively ancient (though perhaps not so ancient as he imagines) semi-civilisation of these Luango people. It is remarkable how much their ideas regarding their royal families, their kings and chiefs, resemble the customs of Uganda or of the Mwato Yanvo empire in south-central Congoland. There are also similar ideas of totemism or the division of society into cliques and coteries, each with its emblem or ancestral crest, such as the large Cephalophus antelope, the chimpanzee, pig, otter, francolin (which Mr. Dennett miscalls "partridge"), and domestic goat. Though Mr. Dennett does not cite the mushroom as a totem, it appears to be regarded as possessing mystic qualities (as in Uganda). He gives a native equivalent for "totem" as "china" (which he mis-spells *xina*), plural "bina." This word he also renders as "prohibition." It is apparently related to the widespread Bantu root *kina* or *bina*, to dance, such dancing being of a ceremonious or religious nature, and often used to illustrate the action or the object which should be avoided by the persons concerned.

It is also interesting to notice that the word for sacred grove or specially preserved forest in Luango is the same as in the languages of the Victoria Nyanza, *chi-bila*, *bi-bila* (in East Africa this word is pronounced *-bira*).

Mr. Dennett deals exhaustively with the omens of birds, frogs, dogs, and snakes, also the remarkable connection of the rainbow and its primary colours with certain specified serpents supposed to represent each colour. He describes all the sacred animals (and the folk-lore concerning them), also the names of the four days of the week (for, as in most parts of negro Africa, the week contains only four days), the names of the seasons, native ideas of astronomy and natural history (the details about the life of the chimpanzee are particularly interesting).

Somewhat similar information is given about Benin. Both in regard to the Bantu people of Kakongo and the West African negroes of Benin Mr. Dennett supports his opinion by citations of the native languages, which (overlooking an exasperating orthography) are almost invariably correct. In some cases he does not seem quite to have grasped the meaning of words. For example, *Nzambi mpungu* really means the God of the Firmament, though this is not quite clearly stated by Mr. Dennett, who has not realised that *mpungu* is only a variation of the East African Bantu *mwingu*, from a root (probably originally *-pingu*) meaning the sky, the heavens, the region in which rain falls from the clouds.

The reviewer cannot accept Mr. Dennett's etymology of the Bantu phrases he attempts to explain. He would read into them a philosophy which is altogether misleading. An acquaintance with other and cognate forms of speech would have shown him this.

For the mass of the book, however, the reviewer has nothing but praise, but he must enter here an emphatic protest against the unreasonable orthography adopted in the case of the Luango or Kakongo language (but not as regards the Bini tongue). For the consonant *c* or *ch* (the sound of *ch* in *church*) Mr. Dennett uses the letter *x*. Most transcribers of African tongues have agreed to adopt the single letter *c* to express the combination *tsh* or the palatal *k*. Some missionary writers have made use of the letter *x* in its Portuguese interpretation for the sibilant *sh*. It is a great pity that even this should be done, for if *x* is to be used at all it might preferably be employed to express the combination *kh*, the guttural *ch*, but to transfer this needlessly for *c* or *ch* is a serious stumbling-block to the reader. There are

Mavunga, a Kabenda nail fetish. From "At the Back of the Black Man's Mind."

other points (which it would be wearisome to discuss in detail as regards the transliteration of these Bantu dialects in Mr. Dennett's book) that hinder and confuse. It is such a valuable contribution to ethnology that one could almost wish a second edition might be brought out with a revised and reasonable orthography—from which, for example, such blots as "Fjort" might be removed. This is the way in which Mr. Dennett for many years past has chosen to spell the Congo word *fi-ote*, which means "a black man."

JUJUTSU [1]

THIS work gives most clearly and concisely an idea of the fascinating art of jujutsu. It is written with the idea that anyone having had a few lessons may continue the exercises, or throws, without the constant help of a teacher, though to learn from the description only would be quite impossible.

Sir Lauder Brunton has given an admirable preface, from which it may be inferred that the medical profession thinks highly of jujutsu as a matter of exercise for both sexes. He says:—"By it not only is every muscle strengthened, but the highest centres of the brain are developed, those whose functions are perception, discrimination and decision."

Japanese wrestling, or jujutsu, differs entirely from the English form of wrestling, which is more or less a trial of strength. In jujutsu it is a question of quickness and brains; the throws are given by taking advantage of the opponent's movements, so that as the attacker advances the opponent trips him up, or gives the throw, by profiting by the momentum of the attacker's body, placing his foot, leg, or arm in such a position that the attacker cannot save himself from falling. In fact, the momentum of the attacker is used to his own detriment.

FIG. 1.—First position of the Uchimata, showing the lifting pull of the thrower's right hand. From "The Fine Art of Jujutsu."

In commencing, the pupil learns to give the "Laudori Kata," which form the basis of nearly fifty methods of defence against various attacks, and not until the pupil has had many lessons is he or she allowed to learn how to take a fall. There is as much to learn in taking the falls as in giving them, and, provided he follows the teacher's instructions exactly, he need not be afraid of getting hurt.

After several of the throws have been separately mastered the pupil is taught to put them in practice in the "loose play," and here it is that the real delight of jujutsu commences, for all his faculties must be alert; he may trip up his teacher with an ankle throw, or, taking advantage of some side movement, may give the "Hizagurama" or trip from the side of the knee, or he may turn sharply round and give the shoulder throw, bringing his opponent over his shoulder on to the ground. Then, when well advanced, the pupil takes his chances against his teacher, and the struggle to put in a throw on either side becomes very exciting.

One great delight of these exercises, as mentioned in the preface, is the extreme accuracy which is absolutely necessary; if a certain movement is not done correctly it cannot be done at all. If the opponent fails to take advantage of the movement of the attacker at the right instant it is impossible by main force to effect a throw.

Perhaps the most difficult throws are those given in Figs. 44 and 45, which are here reproduced, called the "Uchimata," for it requires immense practice to get the balance necessary to gain the second position.

Besides the throws, there are many locks which are most effective in overcoming an opponent. Fig. 111 and the following series represents one of these in detail, by which, when used in self-defence, it is not difficult to break the elbow of the attacker.

In addition to the jujutsu described in these pages

FIG. 2.—Second position of the Uchimata, showing the full fling up of the thrower's right leg while standing poised on the left. (From "The Fine Art of Jujutsu.")

there is another form, which consists in wrestling on the ground, where the throws are given and are finished by a lock on the ground, but this is such a very rough form of exercise that it is not described in Mrs. Watts's book.

We have not yet alluded to the excellent illustrations by that well-known amateur photographer Mr. G. W. Beldam. Without them the text would be impossible to follow, and to have caught the different positions so exactly shows immense patience and ability on his part.

T. MARY LOCKYER.

SCIENTIFIC WORK IN EGYPT.[1]

THE work of the Survey Department in Egypt embraces many inquiries outside those usually identified with geodetic measurement. The department is responsible for the conduct of a laboratory in which analyses of rocks, ores, and minerals are made for the Geological Survey, where the illuminating

[1] "The Fine Art of Jujutsu." By Mrs. Roger Watts, with 141 Action Photographs by G. W. Beldam. Pp. viii+146. (London: W. Heinemann, 1906.) Price 6s. net.

[1] "A Report on the Work of the Survey Department in 1905." By Capt. H. G. Lyons, F.R.S., Director General. [illegible] 6+plates. (Cairo: Al Mokattam Printing Office, 1906.)

power of the Cairo gas is determined, and where paint, oils, cement, asphalt, &c., are tested for commercial purposes. Further, the purity of the water supply of Cairo demands constant attention, while the river water and the silt which the Nile carries in suspension during a large portion of the year have to be repeatedly examined. These are matters which must be passed over with a bare mention, though doubtless the management finds the addition of such investigations sufficiently exacting.

More immediately connected with the work of the department appear to be the hydrographic survey of the Nile and river gauging. For the efficient examination of questions connected with this subject a permanent gauging station has been erected at Sarras, thirty-three miles below Wady Halfa, and here are measured in various ways some of the factors that determine the quantity of water in the river. The work is hardly out of the experimental stage at present. A main object is to determine the most appropriate kind of apparatus that will give accurate results with the least expenditure of labour. This section is very interesting, and tables are added showing the volume of water discharged in cubic metres per second, and the mean velocity per second, with other details. The velocity and volume both increase up to the end of August, when, unfortunately, observations were discontinued, though the time of maximum was not reached. A preliminary discussion of the results has shown that the volume of the discharge at Khartoum, when the Atbara was not contributing, was greater than that at Aswan by amounts which could not be explained by loss from evaporation or from use in irrigation. The cause of the loss is not yet decisively explained, though Captain Lyons makes a plausible suggestion.

Another feature of the report is the description of the Helwan Observatory, which seems to be very fairly equipped with magnetic, meteorological, and seismological instruments. Of the astronomical portion, we learn that the 30-inch reflector presented to the Egyptian Government by Mr. R. H. Reynolds, of Birmingham, is in course of erection, and that all the heavy castings are in position. Some of the mechanism has been returned to England for alteration, and the completion of the erection awaits the return of these essential fittings.

Of the geodetic work properly so-called, details are given of the second order triangulation with all necessary fulness. The standard of accuracy attained is not quite that of the highest order, but sufficient for the object for which the measurement was undertaken, namely, the control of the map sheets used in the revenue survey of the country. It is now possible to base a map of Egypt on a connected triangulation from Damietta to Wady Halfa, an extent of nine degrees. Of even greater importance, however, is the triangulation, which it is to be hoped will be ultimately carried out, whereby Egypt will contribute to the measurement of the arc of meridian, which in its entirety will extend from the Cape of Good Hope to the North Cape, along the thirtieth parallel of east longitude. For several years Sir David Gill has been engaged in carrying this chain of triangulation northward, and the prospect of completing a measured arc of some 100° of latitude cannot but be of profound interest to the astronomer, the geologist, and the physicist. Captain Lyons, however, is fully aware that the value of such a work consists very greatly in the maintenance of the same standard of accuracy throughout. The most difficult problem of geodesy, he tells us, is to pass from a particular platinum and iridium bar, on which the length of the metre is defined, to the length of a base line over a more or less rough land surface with as great an accuracy as possible. Viewed in this light, the most interesting portion of the report consists in the description of the method of the comparison of the bars and Jaederin wires used in Egypt. The accuracy seems quite satisfactory.

W. E. P.

INTERNATIONAL FISHERY INVESTIGATIONS.[1]

THE results of the first two or three years of active investigation in connection with the general scheme of fishery research, which is being carried out in the seas around north Europe under the auspices of the International Council for the Exploration of the Sea, are now being rapidly published in a series of reports issued in part by the Bureau of the International Council and in part by the authorities of the different countries participating in the international scheme. As the outcome of the work is being thus gradually brought to light, the comprehensive character of the programme becomes increasingly obvious. The remarkable scientific interest of the results obtained from what is probably the greatest and most serious attempt yet made to carry out a scientific investigation by means of international cooperation is placed beyond dispute, nor can it be doubted that the eventual practical benefit of these researches will be of even more importance and of much direct value to the fishing industry.

The first report under review contains detailed accounts of some of the work carried out in 1902 and 1903, whilst in the Marine Biological Journal Mr. James Johnstone, of the Liverpool University Fisheries Laboratory, gives a useful *résumé* of the results published up to the summer of 1906. The remaining reports deal for the most part with more recent publications.

As must be by this time well known, three main lines of research are being developed in the international scheme, the hydrographical, the biological, and the statistical. The hydrographical investigations record and endeavour to explain the constantly changing physical conditions under which fishes pass their lives, the biological investigations aim at a complete account of the life-history of the more important food fishes as well as a detailed knowledge of the various smaller marine creatures which serve as the food of fishes, the statistical investigations deal primarily with the variations in the actual quantities of fish removed from the different fishing-grounds and brought to market, and at the same time yield considerable material which is capable of supplementing and amplifying the knowledge of the history of the fishes obtained from the biological observations. Although the three branches of the investigation are for practical reasons carried out more or less independently, the ultimate success of the work depends upon the judicious combination of the knowledge gained from each, and its application to particular problems of the fishing industry.

A striking example of the success of such a combin-

Journal of the Marine Biological Association of the United Kingdom, vol. vii., No. 5.

ation is contained in Dr Johansen's paper on the plaice fishery of the Kattegat, and the means whereby it may be improved (*Rapports et Procès-Verbaux*, vol v, p 45) From a study of statistical data it is shown that although the intensity of fishing for plaice in the Kattegat, in consequence both of an increase in the number of boats and of improvements in the fishing gear, has increased very greatly since 1885, the actual weight of plaice landed has remained practically stationary from that year until 1904, the year for which the last statistics are available It is only a rise of about 200 per cent in the price of plaice that has enabled so many boats to continue profitable fishing, but although the total weight of fish has neither increased nor decreased during the period mentioned, there has been a marked decrease in the average weight per fish so that the plaice harvest is now composed of a much larger number of smaller fishes than was formerly the case Johansen, following out an idea previously developed by Petersen, shows that at the present time by far the greater number of plaice are captured before they have attained the size at which their value per unit of weight is greatest

Biological investigations carried out in the Kattegat have shown that there are important differences between the plaice populations in the northern and in the southern parts of the area In the northern Kattegat the fish are large and well grown, and attain sexual maturity at a later age and larger size than those in the southern Kattegat This change in the character of the fish population is correlated with the changes in the hydrographical conditions which take place as the Baltic is approached The plaice supply of the southern Kattegat consists chiefly of small fish already sexually mature, that of the northern Kattegat of larger and more valuable fish which have not yet attained maturity

The principal nurseries for young plaice near the Danish coast have been investigated, and the fact that the rate of growth of the fishes on some of these nurseries as determined both by marking experiments and by examination of otoliths, is abnormally low suggests that these particular grounds are overcrowded with young fish This condition is not, however, found in either the Kattegat or Skagerak, and in the southern Kattegat the rate of growth during the first two or three years of the life of the plaice is as rapid as in the northern part, although in later years it becomes much less rapid The experiments with marked fishes which have been carried out on plaice in the Kattegat have shown that far more than 50 per cent of the plaice are re-captured each year, thus indicating a very high intensity of fishing

After a careful review of the evidence gathered from all the different lines of research, Johansen comes to the conclusion that the enforcement of a minimum size-limit for Kattegat plaice of 30 cm (12 inches) would result in an increase in the value of the fishery amounting to from 50 per cent to 100 per cent, although the exact figure can only be determined by experiment Further, since in certain parts of the Kattegat only insignificant numbers of small plaice are found but these grow rapidly, he thinks that the transplantation of large numbers of small fish from more crowded nursery grounds to such places would be worth a trial

A study of Johansen's paper can hardly fail to leave the impression that a great advance has been made towards the solution of the more important problems connected with the plaice fishery of the Kattegat, and that promising practical schemes, based upon a rational understanding of the questions involved, are already in prospect for the improvement of that fishery The Kattegat is a somewhat circumscribed sea-area of moderate dimensions, and it will be scarcely surprising if the end to which all scientific fishery investigations are directed is first achieved there, but the reports before us show that work upon quite similar lines is being rapidly done on the plaice fisheries of the larger region, which may be described as the middle and southern North Sea The summary of the investigations of the German, Dutch, and English naturalists, which is contained in the report of Dr Garstang, the convener of Committee B ("Reports of British Delegates," vol ii, p 191), in that of Dr Redeke (*ibid*, p 265), and in the various statistical papers by Henking (*ibid*, p 127), Hoek (*ibid*, p 300), and Kyle (*ibid*, p 363, and especially *Bulletin statistique*, vol i), foreshadow as complete and satisfactory a solution of the problems in this area as has been, one might almost say, already achieved in the Kattegat

In the larger area the marked-fish experiments have already yielded much valuable information, and it ought not to be long before a fairly complete account is available of the normal migrations of the plaice The transplantation of small plaice from the crowded nursery grounds along the coast to the shallow waters of the Dogger Bank, in the middle of the North Sea, has been attended with a high measure of success, the growth of the transplanted fish having been several times greater on the Dogger than on the inshore grounds An experiment in transplantation upon a very much larger scale is the next step which appears to be called for

The plaice, however, is only one amongst the many fishes which have received attention Much interesting work has been done on the haddock and on the cod, although most of the reports so far published are of a preliminary character only (Hjort and Petersen "Reports of British Delegates," vol ii, p 153)

The herring, too, is receiving attention, and the statistical data brought together by Kyle (*Bulletin statistique*, vol i, p 228), with the accompanying charts give a graphic picture of the movements of the herring fleets, and therefore, presumably, of the fish themselves The attempt already begun to correlate these movements with changes in the hydrographical conditions will almost certainly yield valuable guidance to the herring fishermen, and ought to enable them to avoid much fruitless shooting of their nets

A striking piece of work is Dr Johs Schmidt's contribution to our knowledge of the life-history of the common eel (*Rap et Proc -Verb*, vol v, p 137) Grassi and Calandruccio had already followed, from specimens taken in the Straits of Messina, the different stages in the metamorphosis of the eel larva from *Leptocephalus brevirostris* to the young elver, and they had suspected that the natural home of the Leptocephali was in deep water, their occurrence in the Straits of Messina being due to the peculiar nature of the currents and the upwelling of water from the deeps Schmidt's researches, carried out on the Danish investigation steamer *Thor*, to some extent confirm this view, rendering it at the same time more precise, and the spawning grounds of the European eel and the home of the eel larvæ are now for the first time made clear It is along the edge of the continental slope, to the west of the British Isles, that the young eel larvæ (*Leptocephalus brevirostris*) are found in large numbers, in regions where the depth of the water is about 500 fathoms and the bottom temperature is at least as high as 7° C The larvæ themselves are not, however, near the bottom,

but occur chiefly in the upper and middle water layers, being found during the daytime in greatest numbers about 50 fathoms below the surface. The inference is obvious that the female eels spawn on the bottom in the same or a neighbouring area to that in which the larvæ are taken. The highest point of larval development seems to occur in June, the Leptocephalus has then ceased to feed, and the next stage of its existence is a long, retrogressive metamorphosis, during which it decreases in size in all dimensions, and gradually takes on the slender eel-like form. During the latter part of the metamorphosis the larvæ, or elvers as they may now be called, become very active, and commence their great migration towards the coast and the fresh waters in which they feed and grow. The whole process of metamorphosis occupies about a year, and during this time the young eels take no food at all.

Schmidt has obtained information from localities all along the west coast of Europe, from Spain to Norway, as to the time of year when the young elvers first appear in the rivers, and the interesting fact comes out that the time of occurrence of the elvers on the different coasts depends, in the first place, on the distance from the deep water in the Atlantic where the eels spawn. On the coasts directly washed by the ocean the ascent into fresh water begins between September and December, or even in January or February, according to the distance from the deep water, whilst on the coast of Denmark and in the inner Danish waters the elvers do not arrive until April and May.

The whole story of the life of the common eel, as now made clear by these investigations, is one of the most fascinating which it has fallen to the lot of any naturalist to unravel. We can picture the great shoal of parent eels, the long journey from the inland waters ended, arriving at their proper spawning places in the deep Atlantic along the whole length of the European coast, the floating eggs gradually developing into transparent, deep ribbon-shaped Leptocephali, the slow transformation to slender, active elvers, the vast multitude of elvers, foodless, their whole energy concentrated and spent in locomotion only, moving steadily in towards the coast, entering the rivers of Ireland and of France, entrapped in the great funnel of the Severn's mouth, pressing on through the English Channel and into the North Sea, a remnant only, when tribute has been paid to all the rivers by the way, reaching the fresh waters of Denmark and the Baltic coasts, and, finally, the feeding and growth of the eels all over the European continent in preparation for the return migration to the sea.

There can be little doubt that this new knowledge of the life-history of the eel will lead to results of great practical value to the eel fisheries of Denmark. The fact that one large market for Danish eels is in London makes the question one of practical interest to this country also. In the first place Schmidt points out that since Denmark and the Baltic depend for their supply of young eels upon the general European stock coming from the Atlantic, any protection of the adult fish in Danish waters is quite uncalled for, since even if all the Danish and Baltic eels were caught, only an insignificant reduction in the number of eel larvæ in the deep waters of the Atlantic would result. In the second place, since the evidence seems to show that the main supply of young eels to the Baltic comes from elvers which have travelled through the English Channel, and not around the north of Scotland, only a remnant of the great shoal of migrating elvers reaches that coast, a view which is confirmed by the fact that in Danish rivers no such immense runs of elvers are known as are found in the Severn or in the rivers along the Atlantic sea-board. It would seem that whilst the latter rivers, owing to their geographical position and configuration, receive far more elvers than they are able to support, those of Denmark and the Baltic may have a deficient supply. Schmidt recommends, therefore, that elvers should be taken from the western rivers (elvers caught in large quantities in the Severn are sold at from 1d. to 2d. per pound, and one pound contains about 1500 individuals) and transferred to the Danish rivers and to the Baltic, where they are wanted, and where there is room for them to grow into large eels.

Lack of space precludes us from describing in the same detail as we have done for the plaice and the eel the work which is in progress in connection with the other food-fishes. Heincke's report on the occurrence and distribution of the eggs, larvæ, and various age-groups of the food fishes in the North Sea (*Rapports et Procès-Verbaux*, vol. iii.) and the papers by Hjort and others on the life history of the haddock and cod already referred to clearly indicate results which may eventually be of even greater interest and importance than those described above.

It seems impossible, after an impartial consideration of the volumes before us, to come to any other conclusion than that the International Fishery Investigations are being conducted with marked energy and enthusiasm by all the countries engaging in them, and that the great conception of an international cooperation of men of science having for its object the acquirement of the knowledge necessary for the rational exploitation of the sea on a scientific basis is in a fair way to justify itself in the eyes of the world.

NOTES

On Monday last the Duke of the Abruzzi delivered to a large audience in the Argentine Theatre at Rome a lecture on his expedition to Ruwenzori, and was awarded the gold medal of the Geographical Society of Italy. The King and Queen of Italy were present with their full Court, and the Diplomatic Corps and chief officers of State also attended. The lecture will be repeated at a special meeting of the Royal Geographical Society to be held at the Queen's Hall, Langham Place, on Saturday, when the King and the Prince of Wales have signified their intention to be present.

We regret to announce that Mr. Cornelius O'Sullivan, F.R.S., known chiefly by his investigations on scientific aspects of brewing, died on January 8, in his sixty-sixth year. We regret also to learn of the death of Mr. T. R. Dallmeyer, head of the famous optical firm, and formerly president of the Royal Photographic Society.

Major F. H. Hills, C.M.G., R.E., who has been appointed to inspect and report upon the survey departments now working in the protectorates of British East Africa and Uganda, has just left England for Mombasa. On the completion of the above-mentioned work he will proceed to Colombo to make a similar inspection in Ceylon.

A new Government farm, to be devoted wholly to tobacco research, is to be opened, says the *Pioneer Mail*, in the Rangpur district of Bengal, which is believed to contain perhaps the most important tobacco-growing area in the whole of India, the climate and soil in certain parts of the district being admirably suited to the cultivation of the crop.

SOLAR halos are not so rare as to be very remarkable meteorological phenomena, but a halo seen complete or in parts in the afternoon of January 4, in various parts of the country, seems to have excited some interest among people unfamiliar with its nature At Hitchin the halo was first noticed about 2 15, and it lasted until about 3 o'clock, three-quarters of a complete circle being visible A complete halo was noticed at Southampton and Worcester about 3 o'clock, and portions were observed near Ealing at 3 20, and at Chichester about 4 o'clock

ON Tuesday next, January 15, Prof Percy Gardner will deliver the first of two lectures at the Royal Institution on "The Sculpture of Aegina in Relation to Recent Discovery," and on Thursday, January 17, Dr W N Shaw will begin a course of two lectures on "Recent Advances in the Exploration of the Atmosphere" The discourse on January 18 will be delivered by Sir Andrew Noble, Bart, K C B, on "Fifty Years of Explosives" Prof W W Watts being unable to deliver his two lectures on the "Building of Britain" and "Recent Light on Ancient Physiographies" on Thursdays, February 14 and 21, Mr Alfred Harker will deliver two lectures on those dates on "The Minute Structures of Igneous Rocks and their Significance"

A MAGNETIC survey of Mexico is now in progress under the joint auspices of the Mexican Government and the Department of Terrestrial Magnetism of the Carnegie Institution of Washington It is reported in *Science* that the Mexican Government has two parties in the field under the direction of the Observatorio Astronomico Nacional Mexicano one having charge of the eastern part of the country and one of the western part, embracing the Pacific coast from Manzanillo to Guaymas, inclusive of Lower California The Carnegie Institution party will confine operations to the part of Mexico north of the twenty-fifth parallel upon the completion of which it will proceed to Campeche, Yucatan, and the Central American countries It will be possible within the next year to construct accurate magnetic maps for the region between the parallels of latitude 20° and 49° north and meridians of longitude 65° and 125° west of Greenwich

THE Harvard ethnological expedition to South America is now on its way to Arequipa, Peru, where it will make its headquarters for three years It consists of Dr W C Farabee a Harvard instructor in anthropology, with two assistants Mr I J de Milhau and Mr J W Hastings, with Dr Edward F Horr as physician to the party Its main object is to collect all possible information about the little-known Indian tribes living on the headwaters of the Amazon and Parana on the east of the Andes The only previous exploration in this region was that of Dr Flick, a German man of science, who, however, covered only a small part of the territory that will now be visited The expenses of the expedition will be met by a recent Harvard graduate The Secretary of State has provided letters of introduction to various officials in South America, and assistance is also expected from the Harvard Observatory at Arequipa Another scientific expedition in which Harvard is interested is that which Prof Alexander Agassiz is projecting for February, when he will take a small party in a steam yacht for a cruise in the West Indies

THE University of Michigan has come into possession of a tract of land which is to be developed into a garden meeting all the requirements of the present-day European botanic gardens We learn from *Science* that the ground comprises about thirty acres, and is separated from the Huron River by an approximately equal area owned by the city of Ann Arbor By an agreement entered into by the University and the council of the city, the two pieces of land are to be developed as one, thus ensuring a garden and park of at least sixty acres The following four aims for its use will be observed in the development of the garden —(1) teaching, in which students are instructed in the various orders and functions of plants, (2) scientific, in which genetic relationship is studied and experimental work is carried on, (3) economic, in which collections of medicinal and economic plants are made, and the effect of horticulture and agriculture is shown, and (4) æsthetic and popularly educational, in which special provision is made to make the plantings, the drives, and walks of interest and value to the public

AN obituary notice of Prof Ernesto Cesàro is contributed by Prof Ernesto Pascal to part xvii of the current number of the *Rendiconti* of the Lombardy Institution Cesàro was born at Naples on March 12, 1859, and went to study in the School of Mines at Liége, where his brother had previously been appointed professor of mineralogy He soon developed a taste for mathematics, and began to publish papers in *Mathesis* and elsewhere In 1886 he presented more than a hundred papers in competition for university prizes at Messina on infinitesimal calculus, and at Naples on complementary algebra, and six years later, in awarding him the gold medal of the Italian "XL" Society, Beltrami alluded to about 200 papers, many of considerable length from his pen Cesàro returned from Belgium to study mathematics at Rome, but never consented to present himself for examination for the university degree In 1886 he was appointed professor at Palermo, and was awarded an honorary degree by the University of Rome at the early age of twenty-seven In 1891 he was transferred to Naples His works deal with arithmetic, theory of functions, algebraic analysis, theory of elasticity, intrinsic geometry and infinitesimal calculus On September 12, 1906, he was bathing with his son at Torre Annunziata when a wave struck the boy In attempting to rescue him the father was struck on the head, and both father and son perished together

WE have received a copy of an address delivered by Prof Carl Rabl director of the Anatomical Institute at Leipzig, before the university of that city on June 21 1906, and entitled "Uber 'Organbildene Substanzen' und ihre Bedeutung fur die Vererbung" (published at Leipzig) One of the chief subjects discussed is the theory of the continuity of the chromosomes, that is to say, of the chromatic elements of the nucleus of the germ-cell In conclusion, it is argued that the development of an organism must be regarded as a continuous chain of chemical progression, based upon and regulated by a definite anatomical substratum

THE report of the Bristol Museum and Art Gallery for 1906 chronicles the results of the first complete year's working of the combined institutions, and it is satisfactory to learn that in every respect the authorities have reason to congratulate themselves on their efforts The public has responded in an almost surprising manner to the attractions offered, the attendance during the year having exceeded half a million In the natural history section groups of birds, both British and foreign, as well as one of tigers, have been set up for the museum by Rowland Ward, Ltd, and have proved highly attractive In the list of big-game trophies the name of one animal is given as the "Burmese buffalo or gaur," which leaves

the reader in a happy state of ignorance as to the species really referred to

The whole of the second part of vol vii of the Bulletin of the Tokyo College of Agriculture is devoted to silk-worm culture and problems connected therewith, all three articles being from the pen of Mr K Toyama Breeders, it appears, have a belief that if a male moth is mated with more than one female, the product of the later unions will be feeble The author finds, however, that polygamy is a normal condition of the species, and that the reputed ill-effects of this habit are non-existent The study of a fly parasitic on silk-worms forms the subject of the second article In the third, the conformity or otherwise of hybrid silk-worms to the Mendelian law is discussed Careful investigation has shown that, as regards the colour of the cocoons and eggs and the nature of the larval markings, Mendel's law is followed, although in respect to the shape of the cocoons and the brood-characters no adherence to this can be detected

In the twentieth annual report of the Liverpool Marine Biological Committee, or in other words, the Marine Biological Station at Port Erin (Isle of Man) reference is made by Prof Herdman to the urgent need of a steam-yacht for local collecting For two months such a vessel was privately chartered, and employed in experimenting on the kinds of nets best suited for collecting micro-organisms, but, unfortunately the funds at the disposal of the committee do not permit the permanent engagement of a steamer The aquarium continues to form a great attraction to visitors, of whom more than 15 000 were recorded during the summer Several invertebrates new to the fauna of the Irish Sea have been collected The suitability to their purpose of the tanks is demonstrated by the fact that several organisms have made their appearance spontaneously, having gained entrance by way of the supply-pipes, some of which were blocked by the invasion Care has to be taken in regard to placing animals together as one rare anemone was devoured by a commoner kind, while it was found that the worm Nereis is in the habit of dragging Sabellæ from their tubes The fact that the lugworm can swim is a new discovery Prof Herdman's address on "Some Problems of the Sea," referred to in our issue of last week, forms an appendix to the report

In the January issue of the *Century Magazine* Prof H F Osborn describes a find of prehistoric crania from a mound in Douglass County, Nebraska Of the six skulls discovered, two from an interment near the surface of the mound were of the modern Indian type, but beneath these, and covered by a layer of ashes resting on a stratum of silt compacted by the fire above, four skulls of a remarkable character were unearthed The only implement found with them was a small, broken, triangular flint knife Unfortunately, the back part of each of these crania is wanting, but the portions which remain exhibit low cranial capacity, and are believed to approximate to the Australian type The supra-orbital ridges are not more pronounced than those of the Australian, but the forehead is even more flattened and receding These skulls, which have been deposited in the museum of the University of Nebraska, indicate a race of low cerebral capacity, inferior to the modern Indians or the typical American mound-builders Their average stature was about 5 feet 10 inches Compared with typical primitive forms—those of the Javan *Pithecanthropus erectus* that of Gibraltar, and the Neanderthal skull—the American specimens seem to represent a class more recent than the last It would be rash to speculate on the importance of this discovery until the missing portions can be recovered or more perfect specimens unearthed "Even if not of great antiquity," says Prof Osborn, "it is certainly of a very primitive type, and tends to increase rather than diminish the probability of the early advent of Man in America" The same issue of this magazine contains President Roosevelt's enthusiastic account of ancient Irish Sagas, in the course of which he takes occasion to advocate the foundation of chairs of Celtic in the universities of America

The latest issue—a double number—of *Le Bambou* dated mid-December completes the first volume The articles include a note on the indigenous localities of species of Phyllostachys, an account of the vegetative development of bamboos, and a report on the growth of the species cultivated at Ermitage during the year

Among the papers read before the Botanical Society of Edinburgh, and published in the second part of vol xxiii of the Transactions and Proceedings, Mr J A Alexander communicates an article on the flora of Portuguese East Africa with illustrations detailing the more conspicuous plants The dominant order is Compositæ containing several species of Vernonia Helichrysum and Senecio but the Leguminosæ and Euphorbiaceæ are more interesting and useful Of Landolphia rubber vines only the species *florida* and *petersiana* are mentioned An account of the extra-tropical trees planted and grown in Arran by the Rev D Landsborough testifies to the mildness of the seasons in parts of Scotland, as the list includes species of the Chamærops palm the palm-lily Cordyline Eucalypts, and numerous bamboos measurements of the height and girth of the trees are recorded The discovery of an evergreen Cystopteris by Mr W Young in Aberdeenshire that receives the name of *C fragilis* var *sempervirens*, is noteworthy

It is annoying but often necessary when the names of a group of economic plants are revised to find familiar designations displaced by others more justifiable The limits of the genus Andropogon have always been uncertain and consequently in working out the nomenclature of the oil grasses of India and Ceylon, to which subject the whole of the eighth number of the *Kew Bulletin* is appropriated Dr O Stapf has found it necessary to transfer ten species to the genus Cymbopogon, to re-christen the species *muricatus*, better known as "khas-khas," by the name of *Vetiveria zizanioides* and to retain under Andropogon only the insignificant species *odoratus* This however, is only a portion of the tangle Dr Stapf has endeavoured to unravel The following names are given to the commercial oils —citronella oil is *Cymbopogon nardus*, lemon-grass oil is *C citratus*, the lemon grass oil of Malabar or Cochin becomes *C flexuosus*, Rusa grass or palmarosa oil *C martini* and *C schoenanthus* is limited to the "izkhir" of Arabia that receives the appellation of camel-grass oil

In the Journal of the Franklin Institute (vol clxii, No 6) it is announced that Mr F G Acheson, of Niagara Falls, has succeeded in making soft graphite artificially Hitherto the artificial product has been hard graphite which has been used in the manufacture of electrodes and as a pigment The soft graphite will be used as a lubricant, as a stove polish, for electrotyping and for coating gunpowder

The *Pioneer Mail* of December 14, 1906 directs attention to the extraordinary development of the manganese ore industry of India since the discovery in 1890 by Mr

H G Turner of the commercial value of the manganese ore in the Vizianagram district of the Madras Presidency It is evident that India will soon stand first as the largest producer of manganese ore in the world

IN *Concrete and Constructional Engineering* (vol I, No 6) there is an admirably illustrated article dealing with reinforced concrete bridges, by Mr W N Twelvetrees The article on steel and concrete at the Ritz Hotel, London, describes a striking example of steel-frame construction encased in concrete A new use for concrete is indicated in the description of a gas-holder tank of reinforced concrete, 84 feet in diameter and 21 feet deep, at Dubuque

THE annual retrospects published by the engineering journals are of great value for reference to workers in other fields The report on the year's progress published in the *Engineer* of January 4 is the most exhaustive that has appeared It covers the domains of mechanical engineering civil engineering water supply, gas supply war material, chemistry, metallurgy electrical engineering and sanitary engineering In the special field of mining and metallurgy the report in the *Mining Journal* of December 29, 1906 is the most complete The report on shipbuilding, in *Engineering* of January 4, shows that the past year has been very remarkable so far as marine construction is concerned The tonnage produced in the United Kingdom 2,030,990 tons, is the highest yet reached

WE have received from Mr U S Grant a copy of a report he has prepared for the United States Geological Survey (Bulletin No 284) on the mineral resources of Prince William Sound, on the north side of the Gulf of Alaska Two mines on the shores of the Sound have demonstrated that copper ore of good grade occurs in the district Erosion in very recent time has been general, so that no considerable secondary concentration of ores exists The ores of possible commercial importance have all the characteristics of primary deposits and irregularity of form is to be expected Developments should consequently be confined to following the ore

THREE memoirs (*Boletins* Nos 40, 42 and 43) issued by the Corps of Mining Engineers of Peru afford striking evidence of the careful attention that is now being devoted by the Peruvian Government to the subject of irrigation In *Boletin* No 40 Mr G I Adams discusses the distribution of water in the departments of La Libertad and Ancachs the memoir being accompanied by a coloured hydrological map In *Boletin* No 42 Mr A I Stiles gives the results of a careful technical investigation of the lagoons of Huarochiri, in the department of Lima He appends a contoured map showing the position of the lagoons and a map illustrating his scheme for increasing their capacity In *Boletin* No 43 Mr C W Sutton and Mr A I Stiles deal with the water supply of the department of Piura

THE United States Geological Survey continues to devote special attention to the investigation of the mineral resources of Alaska The resources of Kenai Peninsula in the most northern portion of the great upward bend of that part of the Pacific coast line enclosing the Gulf of Alaska, form the subject of an interesting report by Mr F H Moffit and Mr R W Stone (Bulletin No 277) The former deals with the goldfields of the Turnagain Arm district, where gold in the stream gravels is very unevenly distributed, and the latter describes the coalfields of the Kachemak Bay region, where lignites occur in beds ranging up to 7 feet in thickness, but of low heating power The geology and coal resources of the Cape Lisburne region are dealt with by Mr A J Collier (Bulletin No 278) The coals are of two classes, low-grade bituminous coal of Mesozoic age and high-grade bituminous coal of Palæozoic age The Mesozoic coalfields cover an area of more than 300 square miles, and contain at least 150 feet of coal distributed in forty or fifty seams, ten of which are more than 4 feet thick The Palæozoic coals occur in limited areas, and the beds are much crumpled and broken, but on account of their good quality will in the future contribute an appreciable addition to the value of the mineral output of Alaska The Rampart gold-placer region in the central part of Alaska is described by Mr L M Prindle and Mr F L Hess (Bulletin No 280) The placers are of two general types as regards their origin, placers of ordinary concentration from the disintegration of the bed rock and placers formed through re-concentration of the gold in older gold-bearing gravels by the cutting of streams The gold of the re-concentrated placers is generally smoother and brighter than that from the others, contains less quartz and iron, and is, therefore, higher in value per ounce The gold has probably come from comparatively small veins distributed through the surrounding rock

A SERIES of experiments has been carried out, the *Pioneer Mail* states, at the Plague Research Laboratory at Bombay with the view of determining the germicidal properties of pure nickel and nickel alloy, and to test the possibility that disease might be conveyed by coins Pure nickel nickel and copper, copper, and silver coins were experimented with and the results are said to show that all the coins had bactericidal action on the plague bacillus

THE law of error forms the subject of several recent papers, including two by Prof C V L Charlier in the *Arkiv fur matematic Astronomi och Fysik* (Stockholm) ii, 8, 15 and one by Prof F Y Edgeworth in the Journal of the Royal Statistical Society lxix, 3 These papers deal with the cases in which the frequency curve consists of a series of terms of which the first term represents the ordinary well known "law of error" and the diagrams showing the effect of the succeeding terms, which Prof Edgeworth reproduces from Prof Charlier's "Researches into the Theory of Probability" will give non-mathematical readers a good general idea of the effect of the corrections on the form of the curve

UNDER the title *Rivista di Scienza*, a new Italian journal is announced dealing with questions of a general nature relative to various branches of science and the connection between them Contemporaneously with the Italian edition, an international edition will be published containing original contributions printed in either of the four principal international languages in which they are written The managing committee consists of Profs Giuseppe Bruni (Parma), Antonio Dionisi (Modena), Federico Enriques (Bologna), Andrea Giardina (Pavia), and Ingegnere Eugenio Rignano (Milan) The editorial secretary is Dr Giuseppe Jona, Milan, Via Aurelio Saffi, 16

THE Decimal Association has recently issued two more pamphlets One, which is sold at 3*d*, gives Lord Kelvin's views on the advantages of the metric system, the opinions of numerous other eminent men, and explanatory tables, the other by Mr S Jackson, is entitled "The Inch Absurdity," and is intended to demonstrate "the utter folly and impossibility" of recent proposals to adopt the

inch, square inch, and cubic inch as standards of length, area, and volume, and the weight of a cubic inch of water at a certain temperature as the standard of weight

THE issue for 1907 of the "Science Year-book, with Astronomical, Physical and Chemical Tables, Summary of Progress in Science, Bibliographies and Diary," edited by Major B F S Baden-Powell, and published by Messrs King, Sell and Olding, Ltd, differs little from that of last year A general article of fewer than ten pages on the progress of science in 1906 has superseded the comparatively full summaries in various scientific subjects given in former years We observe that the "Year-book" can be obtained in an abridged form without the diary

THE twenty-third annual issue of the "Year-book of the Scientific and Learned Societies of Great Britain and Ireland," which has been published by Messrs Charles Griffin and Co, Ltd, provides a convenient short record of the work done by numerous societies and Government institutions in science, literature, and art during the session 1905–6 The information has been compiled from official sources, and the majority of societies and associations included in the volume have demonstrated, by published papers, their activity in extending and disseminating knowledge The editor may be congratulated upon the production of a work of reference which is of distinct service

A PRICE-LIST of invar and its applications, issued by Mr J H Agar Baugh, 92 Hatton Garden, E C, contains some interesting notes on the specific properties of this valuable alloy of nickel-steel Invar is sold in three grades, and the guaranteed maximum of the coefficient of expansion of the middle quality is only 0.0000015 per 1° C, while that of the highest grade is much less For pendulum rods, compensation balances for marine chronometers and pocket watches standard measures of length, tapes for measuring base-lines and many other purposes, invar has proved particularly valuable, and its use in scientific instruments is likely to be greatly extended

THE first number of a new weekly journal known as *Electrical Engineering* was published on January 3 The periodical will deal with the subject of electrical engineering, particularly from the practical and utilitarian aspect, and is intended for the engineer rather than the electrician The number of well-reproduced drawings to scale and of special photographs showing details of constructional work is large, and the paper is, as a whole, particularly attractive Among other articles may be noticed one on the new Great Northern, Piccadilly, and Brompton Railway, and an incidental reference in another part of the paper gives the information that all the rolling-stock for the latest tube is of Continental manufacture If the standard of the first number is maintained, the new periodical should have a successful career

OUR ASTRONOMICAL COLUMN

EPHEMERIS FOR COMET 1906*g* (THIELE).—A further ephemeris for comet 1906*g*, extending to February 16, is given in No 4143 of the *Astronomische Nachrichten* by Herr Georg Dybeck This ephemeris shows that the comet is now (January 10) about 1° north of θ Draconis, and is only about one-third as bright as when discovered

THE OBSERVATION OF TOTAL SOLAR ECLIPSES.—Observers of total eclipses of the sun will find much to interest them in the address delivered by M le Comte A de la Baume Pluvinel to the Astronomical Society of France, and published in the Bulletin for December 1906

The lecturer dealt chiefly with the details of the preliminary preparations which commence at the moment that the astronomer decides to observe the eclipse—usually some months before the actual day—and are not concluded until the observations are actually in progress In eclipse reports these preparations are generally only summarily dealt with and the inexperienced reader will be surprised, on reading the lecture, to learn of the innumerable *minutiae* which *have* to be considered and dealt with if success is to attend the observations The lecturer also named the most famous eclipse observers in the several countries which have participated in these important observations, directing special attention to any exceptional methods employed, as for example, the utilisation of men-of-war and their trained *personnel* by Sir Norman Lockyer at several eclipses

OBSERVATIONS OF MARS.—In the December (1906) number of the *Bulletin de la Société astronomique de France*, M José Comas Sola, director of the Fabra Observatory (Barcelona), gives an illustrated account of his observations of Mars during the opposition of 1905 The following points, among others, are worthy of notice:—On April 26 M Sola saw a "*lac*" at the intersection of Phison and Orontes, and the Euphrates, although perfectly visible, was always diffuse, despite the fact that, at times, the seeing was very good On April 28 changes were observed which were evidently due to atmospheric changes on the planet The "seeing" on May 9 was superb and as shown by the drawing for this date, "*canaux*" and "*lacs*" were seen very distinctly, the latter forming the corners of the pentagon around the Elysium The Propontis was seen to be rather dark and double, with good "seeing," on May 17, at 11h 40m (G M T) but at 12h 40m it seemed quadruple formed by four "*lacs*" disposed at the corners of a square

TRANSIT-CIRCLE OBSERVATIONS.—Parts i to iii, vol iv (second series), of the Publications of the U S Naval Observatory contain a large number of transit-circle observations, with their discussions and reductions

In part i the observations made with the 6 inch transit circle during the period 1900–3 are dealt with and the results tabulated It is interesting to note that whilst the variations of this instrument are much smaller since the substitution of brick for stone piers, they are still important, and Prof Littell from a discussion of the constants for 1903, shows that they are dependent upon the temperature variations The azimuth constant shows a regular annual variation of −0.0115 per 1° F and a diurnal variation of about half that amount In part ii the observations made during 1866–91 are collected and discussed in a uniform manner whilst part iii is devoted to the discussion of the 6 inch transit-circle observations of standard and zodiacal stars made during 1901 and 1902

THE "COMPANION TO THE OBSERVATORY."—Only a few changes are to be noted in the current issue of the indispensable annual the "Companion to the Observatory"

Owing to the continued increase in the number of known variable stars the list of ephemerides supplied by M Lœwy is given in a somewhat different form and the Greenwich mean astronomical time, from noon to noon has been substituted for the civil, midnight to midnight time employed in recent years The addition of stars fainter than magnitude 6.5 has increased the number of lunar occultations given The usual diagram of Saturn's satellites is omitted because their plane passes through the earth during the current year The "Companion" is published by Messrs Taylor and Francis, price 1s 6d

"THE HEAVENS AT A GLANCE 1907"—For all who take an interest in astronomical phenomena and have but little time to spare and but modest instrumental equipment Mr Mee's card, "The Heavens at a Glance" is the handiest and cheapest calendar published As in previous issues it gives the chief events for each month the dispositions of the sun, moon, and planets throughout the year notes on eclipses, meteor showers and variable stars and a pair of star maps by which the observer may recognise the chief constellations and stars at any season of the year The price is sevenpence, post free from Mr A Mee Llanishen, near Cardiff

THE GEOLOGY OF MINING AREAS

MR R G McCONNELL has contributed to the "Annual Report of the Geological Survey of Canada," vol xiv, part B (1905, price 25 cents), a well-illustrated paper of wide interest on the Klondike goldfields The general topography and the communications with other regions are described, and the full-page landscapes convey an excellent idea of the conditions under which mining is carried on Roads have been developed, the White Pass railroad is completed, and it now takes less than a week to reach Dawson City from Vancouver In the latitude of only 60° N, the surface-stratum is continuously frozen, and unfrozen ground is reached at depths of from 60 feet to 200 feet In summer, gravel-beds which are unprotected by moss thaw down to a depth of from 6 feet to 10 feet (p 9) The gold-bearing quartz veins are included for the most part in the Klondike series of schists Microscopic evidence supports the view that these schists are of igneous origin, since a passage is traceable from uncrushed granitoid types to mylonitic sericite-schist (p 19) Cainozoic rocks are found folded in with the schists in Last Chance Creek, thus proving the recency of earth-movement in this area In the basin above Rock Creek these beds contain lignites of Upper Eocene age The low-level gravels of the creeks, which are so important to the gold-miner, include bones of the mammoth, as well as of many existing northern animals (p 29) The greater part, at least, of the Klondike gold is detrital, and is derived from the small but very numerous quartz-veins associated with the older schists (p 61) Many of the grains of alluvial gold enclose quartz, and a few are themselves enclosed in quartz The decay of the rocks must have been enormous to allow of the vast accumulation of auriferous gravels The quartz veins are much younger than the schists in which they lie but are older than the andesites and quartz-porphyries of the district Lode-mining has so far made little progress, but work among the gravels seems still increasing

Mr McConnell has also issued through the Geological Survey of Canada a paper on mineral discoveries on Windy Arm, Tagish Lake, Yukon (1905), where a new mineral district has been opened The quartz-veins here bear a considerable variety of silver ores, ranging from highly argentiferous galena to stephanite and pyrargyrite

In the twenty sixth *Boletín del Cuerpo de Ingenieurs de Minas del Peru* Señor Luis Pflucker describes the gold-bearing deposits of the province of Sandia All the detrital material at the foot of the mountains contains gold, without regard to the nature of the underlying rock The proximity of a moraine formed by an existing glacier makes it probable that the detritus has been brought into the field by glacial action Hydraulic mining is carried on, as may be seen in the illustrations to the bulletin

Mr Harold S Harger brought together a very instructive exhibit of diamond-bearing rocks, and of the minerals associated with the diamond in South Africa, during the meeting of the British Association in Johannesburg in 1905 His paper on the diamond-pipes and fissures of South Africa is now published (Trans Geol Soc of South Africa, vol viii, 1906, p 110), and forms a comprehensive and welcome contribution, certain details of which are sure to meet with healthy criticism Many hundreds of pipes of the Kimberley type are now known to exist, "from the central and northern portions of Cape Colony, throughout Griqualand West, in parts of Damaraland and Rhodesia also north of the Zambezi, and as far east as British East Africa In the Orange River Colony, there is hardly a district between the Wesselton Mine near Kimberley, the Drakensberg Range, and the Orange River, in which the much-sought-for volcanic breccia has not been discovered" The diamond-pipes were opened, in all probability, after the outpouring of the amygdaloidal lava of the Drakensberg, since fragments resembling this rock occur in the "blue ground" of the Jagersfontein Mine From this and other evidence (p 115) Mr Harger conclude that they are of late Triassic or Jurassic age The pipes occur typically in groups, perhaps twenty or thirty near one another, and the large ones seem to contain the truly rich material While some are necks, circular or oval in section, others are mere swellings along lines of fissure, their thinned-out ends being sometimes traceable for miles. Mr Harger discusses the composition of the breccia that fills them, and believes that olivine was not an important constituent of the original mass The analyses quoted from Vogelfontein and the Schuller Mine (p 120) certainly do not indicate a peridotite-magma, though the rock in the Kimberley Mine, on the other hand, yields 32 38 per cent of magnesia The "diamond-fissures," to which special attention is invited by the author, contain a hard basic rock of a less brecciated and more porphyritic character Mr Harger believes that the material in the pipes was injected by explosive action, accompanied by a certain amount of heat, though this was not enough to metamorphose the surrounding rocks distinctly The breccia, in his opinion (p 122), boiled and churned up its constituents in the vent Thus, in opposition to Prof Bonney's view (p 126), he holds that the rounding of such masses as the included eclogite boulders is due to attrition in the pipe Certainly no one who has seen the breccia of a diamond-pipe, such as that of the Schuller Mine, near Pretoria, abutting on its apparently unaltered wall, can associate

FIG 1—Weathered Kantoor Sandstone, Transvaal.

the rock with the phenomena of ordinary igneous flow Equally distinctive is the evidence of the derivation of the green pyroxenes and the garnets, to mention no other minerals, from some previously consolidated and deep-seated mass Few geologists, we fancy, will now dispute the conclusion, first indicated by Prof Bonney when he described the eclogite from Jagersfontein, that the diamond itself is a derived mineral in the pipes and fissures, and arose (p 134) from "an ultra-basic 'carbon-saturated' zone at great depth," through which the "kimberlite" broke The diamond becomes thus linked in our minds with the primitive masses of inorganic graphite, and, still more interestingly, with the nascent carbon dioxide, which still streams upward from the unexplored regions of the crust

In the same number of the Transactions of the Geological Society of South Africa (p 147) direct reference is made to these "juvenile" emanations by Prof Beck, of Freiberg, in a paper on the relation between ore veins and pegmatites The author's purpose is to connect the pegmatites with the aqueous solutions which remain after the consolidation of an igneous mass The old theory of "segregation-veins" is set aside, as has been done by

other writers, and Prof Beck remarks that, since the aqueous solutions in the fissures cooled very slowly, and "their great liquidity was extremely favourable to diffusion of the dissolved substances, crystals of large size are frequently found in pegmatites" While thermal waters found their way to upper parts of the crust, the solutions that resulted in pegmatite-veins represent material retained at considerable depths Hence ore-deposits associated with pegmatites become exposed only after long ages of denudation Prof. Beck cites several examples where tin, copper, and gold are among the substances deposited in connection with pegmatites

Dr G B Trener (*Verhandlungen der k k geol Reichsanstalt*, 1905, pp 366 and 372) is conducting experiments to show that metals undergo diffusion in solid crystalline rocks at temperatures far below the melting points of the metals employed The complete results are to be published in the *Jahrbuch* of the Reichsanstalt as a chapter of the description of the Cima d'Asta, but the preliminary announcements have already aroused discussion Among the curious points raised by Dr Trener, is the resistance of mica to diffusion of metals in a direction perpendicular to its cleavage planes, well-developed mica-schists may thus be practically impenetrable when their foliation-planes are perpendicular to the direction of diffusion

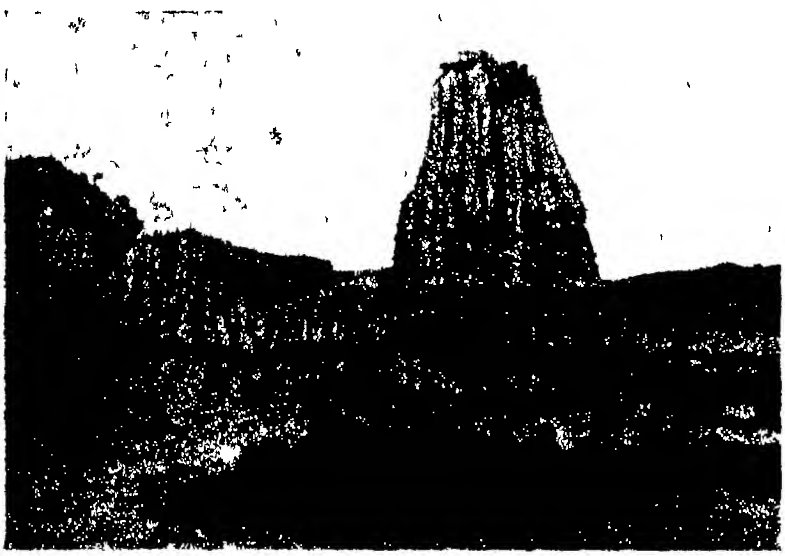

FIG 2 —Earth pillars, south of Alkmaar, Transvaal

The Report of the Geological Survey of the Transvaal for 1904 has been noticed already in NATURE (vol lxxiv, p 646) The volume for 1905 has now been issued, dated August, 1906, liberally illustrated with plates and coloured geological maps and sections, and at the same moderate price of 7s 6d The director, Mr H Kynaston, describes a recent survey of the Komati Poort coalfield, which is conveniently situated on the Delagoa Bay side of the country He reminds us of the record of 25 feet of coal in 33 feet of strata passed through by a bore-hole near Tenbosch Station in 1903, and remarks that this massive seam may underlie the smaller ones that have been proved at various points Arguments are given to show that the horizon of these coal-bearing beds, and those of the Transvaal generally, may be in the Beaufort series, and not in the underlying Ecca series, as has been generally supposed (p 25) Mr Kynaston also describes a Coal-measure series (p 35) in the Bushveld area west of the Pietersburg railway The igneous rocks of this region present many points of interest, especially in the occurrence of bands of magnetite, resembling dykes, associated with, but not passing into, a considerable mass of norite Similar bands are well dealt with by Mr Hall in a later paper in this report (p 73) Our field-inspection of these iron ores, under the guidance of Mr Kynaston, would certainly suggest that they were igneous intrusions of an extremely basic type

Mr A L Hall (p 41) describes the fine country between Lydenburg and the Devil's Kantoor, or Devil's Shop, so called from the fantastic weathering of the sandstone masses near the edge of the great escarpment Gold-mining is carried on in this hilly region, and a lime industry has sprung up near Godwan River Station through the working of secondary deposits of calcite in the dolomitic series Mr Hall, we think wisely, introduces the descriptions of the microscopic characters of his rocks, as explanations of their structure, side by side with the account of their features in the field A rock believed to be a tuff is interestingly recorded (p 53) among the otherwise intrusive igneous masses found in the Transvaal system The fine illustrations to the report show the escarpment of the Kantoor quartzite, with the rapid descent towards the old granite on the east, the gorge in the far younger quartzite of the Pretoria series, between Waterval Boven and Waterval Onder, where the traveller from the monotonous plateau of the Transvaal welcomes the picturesque notching of its edge, and other scenes from this noble region, including the weathered quartzite (Fig 1) of the Kantoor itself

Another photographic illustration (Fig 2) shows the detrital sand resulting from the weathering of the older granite, which is now eaten out into pillars as much as 25 feet high, with sometimes a cake of more resisting rock upon the top

Passing over other papers in this report, as unfortunately must be the case in a general notice, we may mention Mr Mellor's account of the Witbank Coalfield near Middleburg on the main plateau (p 81) The Permian glacial conglomerate has here supplied, during an epoch of denudation, much of the material of the overlying Beaufort (?) Coal measures The coal-seams, one of them being 24 feet thick, are described and illustrated by sections (p 97, &c) The presence of fine muddy layers raises the ash even in some of the workable coal, to 17 per cent, and the ash rarely falls below 7 per cent

Mr Tweddill (p 106), in a handsomely illustrated paper, describes some ruby bearing rocks from the Leydsdorp district, notably a beautiful example consisting of a pale pyroxene, kyanite and finely granular ruby He holds out hopes, if we read him rightly, that ruby may be in time discovered on a scale of commercial importance in the Transvaal G A J C

MEN OF SCIENCE IN AMERICA

THE issue of *Science* for November 23 contains an article by Prof McKeen Cattell on the selection, and arrangement in order of merit, of a thousand American men of science A table was compiled from lists of fellows of societies, biographical dictionaries, "Who's Who," &c, of the numbers of persons engaged in each branch of science It appears that chemists are the most numerous in America at all events, forming 164 per 1000 of all scientific men, zoologists coming a close second with 155 per 1000 Anthropologists stand at the foot of the list with only twenty-three, but neither statisticians nor economists, it would seem, were taken into account Ten leading representatives of each science were then asked to arrange in order of merit a certain number of students of that science, the numbers fixed being roughly proportionate to the totals in the table first compiled The positions assigned by the different judges to every individual were averaged, and the probable error of the average posi

tion of each calculated A general list, including representatives of all the sciences, was also compiled by interpolation, but neither this nor the separate lists are published An interesting table is given showing the divergences between the ten judges in the case of psychology as an illustration The order of merit given by one of the judges is very much more accordant with the average order than those of the others, and they differ considerably *inter se*, though more if we understand the table rightly, in the case of those at the bottom of the list than of those towards the top Of the first hundred scientific men on the list who are eligible, sixty-one are included among the ninety-seven members of the National Academy of Sciences The discussion of the grades and probable errors is continued in *Science* for November 30, and in a third and concluding article in the issue for December 7 Prof Cattell investigates the geographical distribution of American men of science according to place of birth and place of residence The figures as regards the former are extremely striking The production or "birth-rate" of men of science per million of the population ranges from about 109 in Massachusetts—which stands far above the other States—and eighty-seven in Connecticut down to rates of only one or two in several of the southern States It is argued that differences in stock can scarcely be great enough to account for this, and that accordingly the production of scientific men must be largely a matter of circumstance As regards the place of residence, interesting tables are given showing the institutions with which the men of science taken into account are connected The work forms part of an extended investigation which Prof Cattell has now been conducting for some ten years, and on which he has published several previous memoirs

WAVE ACTION IN RELATION TO ENGINEERING STRUCTURES

A PAPER on wave action in relation to engineering structures, by Major D D Gaillard, issued as a professional paper (No 31) of the Corps of Engineers of the United States Army, contains a great deal of information useful to engineers engaged in designing and constructing sea defences and other works subject to wave action

The first part of the book is devoted to a general consideration of the theory of the formation of waves, and to a notice of the information that already exists as to this This as the author remarks, is embraced in so many volumes that the work of comparing theoretical and observed wave characteristics is rendered very tedious The investigations that have previously been made into wave action, and of which the results have been published, relate principally to deep-water waves, whereas there is very little recorded information as to the action of waves in comparatively still water to which engineering structures are exposed

Major Gaillard the author of this book was for several years engaged upon works of harbour improvement on the South Atlantic coast and the Great Lakes of America

Although the waves to be dealt with in Lake Superior are not of the magnitude of those in the open sea, yet the author's observations cover waves of various dimensions extending up to 300 feet in length and 23 feet in height and the results are recorded of several hundred observations of their length, height, period and depth in which they broke and to which their effect extended Numerous examples are also given of the effect of waves in moving large masses of stone and other material The force of the waves breaking on piers, and other marine structures, was measured both by the marine dynamometer of the class used by Mr Thomas Stevenson more than half a century ago and also by dynamometers of special construction made under the author's directions The general type of the Stevenson dynamometer used had discs of from 3 inches to 9 inches, with springs varying in strength from 10 lb to 50 lb for every inch of elongation The greatest dynamical force recorded with these when used at Dunbar, in Scotland, was 7840 lb per square foot with waves about 20 feet high These dynamometers only measure the dynamic, and not the static pressure, and give only a maximum reading for a storm observation, and are affected in their working when there is much sand in the water

The instruments invented and used by the author, besides the Stevenson type, consisted, in one case, of a steel plate, having an area of one square foot, attached to two elliptical springs similar to those used for carriages, the distance between their centres being 6 inches, the reading of the amount of compression due to the action of the wave being recorded by a rod attached to an index which acted on a paraffin surface The instrument, before being fixed, was rated by having weights placed on the plates and noting the corresponding compressions The other dynamometer used by Major Gaillard consisted of a plate covering a square foot attached to a horizontal cylinder filled with water, over the flange of this cylinder was placed a diaphragm of india-rubber ½-inch in thickness having a face of one square foot A ⅜-inch pipe led from the cylinder to a tank located in the observing station on the pier From this pipe there was a communication to a modified form of Bourdon gauge fixed 19 feet above the centre of the diaphragm, and which registered pressures up to 30 lb per square inch Communication with the tank having been shut off, any pressure applied to the diaphragm was transmitted by the confined hydrostatic column to the gauge More than a thousand readings of wave action were taken with this class of dynamometer while the author was in charge of the works but only two storms of consequence were encountered So far as the observations went, the instrument appears to have given satisfactory results

The text is accompanied by a number of illustrations taken from photographs of waves

SCIENCE IN EXAMINATIONS FOR THE HIGHER CIVIL SERVICE

THE kind of education received and the subjects studied by future civil servants must have a great and far-reaching effect upon the influence exerted by the public departments which administer the multitudinous and diverse affairs of our scattered Empire The methods adopted for the selection of such officers must, therefore, be wisely chosen, and in any examinations designed to facilitate the process of discrimination between men offering themselves for these positions the subjects in which candidates are tested must be those appropriately related to the work of the department in which successful candidates will be employed and at the same time, those most likely to test essential fitness for public work These and similar principles have been widely canvassed recently both in public addresses and in the Press Certain changes in the examinations for the selection of Foreign Office clerks and attachés in the Diplomatic Service are to be introduced, and the new regulations have not met with universal approval It will assist clearness of thought first to compare briefly the existing regulations for the appointments concerned with those shortly to come into force

Candidates for clerkships on the establishment of the Foreign Office and for attachéships in the Diplomatic Service will, after July 1, instead of being examined according to special regulations which have governed these appointments hitherto, be required to take the combined examination for open competitions for the Home Civil Service (class 1), India Civil Service, and Eastern Cadetships This decision profoundly modifies the conditions of selection for service in the Foreign Office and the Diplomatic Service In the past there have been nine obligatory subjects—arithmetic, handwriting and orthography English composition, précis writing, French, German general intelligence, geography, and the history of Europe from 1789 to 1880 inclusive In addition, candidates have been able to offer any two of the following languages, viz , Latin, Italian, Spanish Portuguese, Russian, modern Greek, and Arabic In the examination which such candidates will have to take after July 1 next, papers will be set in thirty-two different subjects, from which a selection must be made by the candidate French and German will be the only obligatory subjects, and candidates will have to reach a high qualifying standard in translation, composition, and oral examination in both

these languages Portuguese, Russian, and modern Greek are no longer optional languages The maximum marks to be obtained in each subject are, as a rule, 500 or 600, but 1200 may be scored in each of the two extensive divisions of mathematics included

Though candidates for the appointments in the Foreign Office and the Diplomatic Service may make a selection from the long list of subjects referred to, the number of papers taken must be such that the maximum of marks that can be obtained from the subjects chosen is limited to 4000 Under the new conditions, the man who attempts to train himself by attendance at a cramming establishment, for the sole purpose of succeeding in the competition, will have a much smaller chance of success than a candidate who has graduated in honours after a university course The student who has made himself master of any of the great divisions of knowledge will be able to acquit himself with credit For example 2400 marks may be gained in science, 2400 in mathematics, 1200 in French and German, 1800 in Latin and Greek, 1000 in Greek and Roman history, and 1300 in English and general modern history but in any case the total number of marks attainable in the subjects selected by a candidate must not exceed 4000 The underlying principle seems to be to obtain somehow students who have benefited by a thorough study of at least one department of knowledge, of whatever kind, apparently the intention is to secure men of high attainments, no matter in what subjects they have specialised, and to insist upon a good knowledge of French and German from all candidates

The schedule of subjects is sufficiently comprehensive to afford all ordinary students a fair opportunity to distinguish themselves The candidate who has made science the staple subject of his university course will compete on almost equal terms with one who has studied classics and classical history, while the candidate who has specialised in modern languages and history need be at no disadvantage

The comprehensive subject of geography however, which is at present obligatory is not included among the subjects from which candidates may, after July 1, make their selection, and it is this omission which has given rise to much discussion and many protests In reply to a question on the subject in the House of Commons, the Foreign Secretary said —" Although a knowledge of geography is no doubt very useful it is a subject with which men of general education are generally acquainted and which is easily acquired after entry into the service " Distinguished geographers have since shown how far this is from being the case Sir George Goldie, in an address to the Royal Scottish Geographical Society in Edinburgh published in the *Geographical Journal* for the present month, relates a notable instance of the difficulties to which a want of geographical knowledge may give rise "A good many years ago a territorial arrangement with France was in discussion, and I was invited to consider it The French proposals appeared to the Foreign Office satisfactory, but I found that they were expressed as might have been expected, in longitudes reckoned from the meridian of Paris while the map with which our Foreign Office had considered these proposals was made in Germany and reckoned its longitudes from the meridian of Greenwich The arrangement in question was never completed "

Mr Douglas Freshfield, in his address last Friday to the Geographical Association of which he is president dwelt upon the same point, and said he could give similar instances to that related by Sir George Goldie Mr Mackinder has shown in a recent letter to the *Times* that Sir Edward Grey's description of geography is that of the subject as it was studied twenty years ago and not as it is now understood and taught Substantial reasons have in fact, been given for the inclusion of geography among the other branches of science from which candidates may make their selection

It is hardly necessary to remind readers of NATURE that geography has in recent years taken its place among those branches of knowledge which are studied on scientific lines No geographical teaching is now recognised by the Board of Education as satisfactory in secondary schools unless it has a basis of practical exercises and follows scientific methods The subject has obtained university recognition, and is now taught by practical work in the laboratory and the field As Mr Mackinder has pointed out, "geography has its own modes of thought and its own points of view which are not to be obtained in a hurry " Mr Freshfield was able to point out in his address to which reference has been made, that there is evidence that the Civil Service Commissioners are beginning to reconsider the matter and that it will not be long before the claims of geography will be fully recognised by the inclusion of the subject, dealt with in accordance with modern scientific methods, as one of those in which candidates may present themselves for examination

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD — The natural science board has issued a certificate stating that the work submitted by Mr G F Herbert Smith, New College, is of sufficient merit to entitle him to supplicate for the degree of Doctor of Science

---

WE learn from *Science* that Columbia University and Barnard College will receive 2000*l* each under the will of Mrs Annie P Burgess

SIR W T LEWIS has promised 1000*l* toward founding a chair of mining at Cardiff College, University of Wales provided 30,000*l* is raised in contributions from coal owners, royalty owners and workmen

PROF OTTO BENNDORF, professor of classical archæology at the University of Vienna, died on January 2 at the age of sixty eight years He was well known owing to his works on archæological subjects, and to the excavations he conducted in Asia Minor

ADDRESSING a gathering of science and art students at Gravesend on January 2, the Earl of Darnley is reported by the *Daily Chronicle* to have made the following confession —" I place myself before you as an example of deficiency in education I went through the ordinary public-school course, and received a university education I found myself at twenty two a B A of Cambridge, with a certain knowledge of Latin and Greek, which I have never found of any particular use, but without any knowledge of French, German, or science From my example I hope you will glean some benefit by securing that knowledge which it is now too late for me to acquire "

PROF A SCHUSTER, F R S, has resigned the position as Langworthy professor of physics and director of the physical laboratories in the Victoria University of Manchester Prof Schuster's connection with the University dates from 1871, when he entered Owens College as a student In 1873 he held the post of honorary demonstrator in physics under Prof Balfour Stewart, and in 1881 he was appointed to the newly-created chair of applied mathematics which he resigned to become professor of physics in 1888 Both the Council and the Senate have placed on record by formal resolutions their regret at Prof Schuster's resignation, which is to take effect at the close of the present session and their sense of the very great service which he has rendered to the University by his work as teacher, his direction and administration of the physical laboratories, his contributions to the advancement of science, and the prominent part which he has taken in relation to the re-organisation of the University A general hope has been expressed that Prof Schuster may still remain in close connection with the University and take an active part in its affairs generally, as well as specially in connection with scientific research

PROF E RUTHERFORD F R S, Macdonald professor of physics in the McGill University Montreal has been appointed to succeed Prof Schuster as Langworthy professor and as director of the physical laboratories in the Victoria University of Manchester Prof Rutherford is a native of New Zealand After a distinguished academic career in the New Zealand University he proceeded to Cambridge as an 1851 Exhibition scholar, and entered

Trinity College, prosecuting research in the Cavendish Laboratory He was one of the pioneers of wireless telegraphy, and occupies a high position in the scientific world owing to his experimental work on the ionisation of gases, the discovery of the radium emanation, and the foundation of the now generally accepted theory of radio-activity It is expected that Prof Rutherford will arrive in Manchester early in the summer with the view of taking up the regular duties of the professorship at the beginning of the session in October next

JANUARY has again brought with it conferences of teachers of all grades in various parts of the country In London, large numbers of schoolmasters, schoolmistresses, and educational administrators have met under the auspices of the London County Council, and discussed for three days subjects as various as silversmith's work and the teaching of phonetics In Bradford, the educationists of the north of England have, in well-attended meetings, ranged over the field of education Associations of teachers of special subjects have also held meetings characterised by their enthusiasm Such gatherings are to be welcomed as maintaining an active interest in education, and as likely to send teachers back to their work with renewed energy and broader knowledge It is worthy of note that in none of the meetings has science or mathematics taken a prominent part We have no reason to regard this as indicative of a falling off in the interest in these important parts of the school curriculum it rather directs attention to the fact that in recent years questions concerning mathematical and scientific teaching have dominated the programmes of teachers' meetings, and much thorough discussion has led to improved teaching and obviated, for the present, the need for further argument At the Bradford conference an important session had for its subject the development of technical education in a large manufacturing centre Prof Charnock, of Bradford and Principal Reynolds of the Manchester Technical School, read papers Mr Reynolds said we need more intelligence and more knowledge on the part of our working people He suggested, first, the need for the extension of the age-limit in higher elementary schools to sixteen years There is an advantage in selecting in each of suitable localities of a town one of the elementary schools and giving it an extended curriculum, staffing and equipping it accordingly, such school being fed from the elementary department of the school and from neighbouring elementary schools, and supported by a scheme of scholarships Secondly, the enactment of a law forbidding the employment of young people in working overtime until they reached their eighteenth year, so as to give full opportunity for attending evening classes Thirdly the establishment of one-day courses of specialised instruction in the technical school or college for selected apprentices in engineering and other similar important industries He urged that the present need is a better appreciation of the requirements of general and secondary education so far as to secure a longer school life, and thus a more complete preparation for specialised training

SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 15 1906 —"The Effect of Temperature on the Activity of Radium and its Transformation Products" By Dr Howard L **Bronson**. Communicated by Prof E Rutherford, F R S

A large number of investigators have attempted to alter the activity of various radio active substances by subjecting them to very high and also to very low temperatures Among all these attempts only two, so far as the present author is aware, have apparently given positive results

The experiments now described show no evidence whatever of any change in the activity of the transformation products of radium when they are subjected to temperatures between $-180°$ C and $1600°$ C If any change does take place it is very small and cannot be more than 1 per cent in the case of radium C for temperatures between $-180°$ C and $1600°$ C, nor more than 1 per cent in the case of the emanation or radium B for temperatures between $-180°$ C and $1500°$ C

There is thus removed the only known exception to the general rule, that the activity of radio-active substances is not affected by temperature

"The Photoelectric Fatigue of Zinc" By H Stanley **Allen**. Communicated by Prof H A Wilson, F R S

Hertz's observation that ultra-violet light can facilitate the passage of an electric spark led to the discovery of other photoelectric actions In the earliest experiments on the photoelectric effect of metals it was noticed that the action was diminished by exposure to light Thus Hallwachs, who found that a metal becomes positively electrified under the influence of ultra-violet light, states that "old surfaces no longer show the phenomenon The radiation itself lowers the potential to which the plates can be electrified, so that with any succeeding experiment made with the same surface, the potential obtained is lower, while the rise to it takes place more rapidly, and the decrease is greater than when for the same interval of time between the experiments the plate was not illuminated" This diminution of the photoelectric action is spoken of as the "fatigue" of metals under the influence of light, and has received attention from many physicists

The present paper deals with the manner in which the photoelectric activity of zinc diminishes when the metal is exposed to light

The experiments described show that it is necessary to employ the sum of two exponential terms in order to obtain an adequate representation for the photoelectric fatigue curve of zinc Just as Rutherford has explained the curves of decay for the excited activity of radium and thorium as a consequence of successive changes, so it is possible to explain the present results as due to two consecutive changes The nature of the modifications thus suggested is left an open question

It is also shown that the longer waves of light can bring about a change in the opposite sense, that is to say, they can produce a certain amount of recovery of photoelectric activity

Entomological Society, December 5, 1906 —Mr F Merrifield, president, in the chair —*Exhibits* —A W **Bacot** A specimen of *Catocala nupta*, taken at rest at Hackney, November 9, 1906, remarkable for having two well-developed tarsi on the left fore-leg Also three ♀ specimens of *Lasiocampa quercus*, L, bred from larvæ from Cornwall in 1906 One of these larvæ had been submitted to a pressure of from 11 to 30 atmospheres (405 lb to 450 lb per square inch) on two occasions, a pressure which had proved fatal at once to a frog, used as a control experiment —Dr T A **Chapman** A long series of *Hastula hyerana*, Mill, bred in 1906 from larvæ collected at Hyères, illustrating the spread of melanism in this species, and a diagrammatic map of the neighbourhood to explain its distribution in that area —Dr F A **Dixey** Specimens of *Teracolus omphale*, Godt, bred by Mr G A K Marshall, to show that under arranged conditions of moisture and warmth the wet-season phase might be artificially induced —*Papers* —*Xanthorhoë ferrugata*, Clerck, and the Mendelian hypothesis L B **Prout**.—The diaposematic resemblance between *Huphina corva*, Wallace, and *Ixias baliensis*, Fruhst Dr F A **Dixey**.

Chemical Society, December 20, 1906 —Prof R Meldola, F R S, president, in the chair —A new laboratory method for the preparation of hydrogen sulphide F R L **Wilson**. If a current of hydrogen sulphide is passed over calcium hydroxide a hydrosulphide is formed which can be decomposed by carbon dioxide, a carbonate being produced and hydrogen sulphide evolved —The affinity constants of aminocarboxylic and aminosulphonic acids as determined by the aid of methyl-orange V H **Veley** It is shown that the usual mathematical expressions hold good, namely, those of straight lines, $y=kx$ or $y=kx-b$, or logarithmic curves, $\log y=\log k+x\log a$ Acids which show irregularities in the Ostwald electric conductivity expression $\phi(k)=a^2/(1-a)V_r(a=\mu/\mu_\infty)$ likewise show similar irregularities in the methyl-orange method —Contributions to the study of the calcium phosphates, I, the hydrates of the calcium hydrogen orthophosphates H **Bassett**, jun The author's experiments show that, in all probability, dicalcium phosphate can only form one hydrate

namely, the dihydrate —Contributions to the study of the calcium phosphates, ii, the action of ammonia gas on the calcium hydrogen orthophosphates H **Bassett**, jun —Relation between chemical constitution and physiological action in the tropeines H A D **Jowett** and F L **Pyman**. The authors conclude that Ladenburg's generalisation, which asserts that mydriatic tropeines must possess a benzene nucleus and a fatty hydroxyl in the side chain, cannot be maintained, since it does not hold good in the cases of terebyltropeine or the lactone of *o*-carboxyphenylglyceryltropeine —Some derivatives of salicylic acid H A D **Jowett** and F L **Pyman** Descriptions of cinnamoylsalicylic acid, its methyl and ethyl esters, and quinine salt, and also 3 5-dichloroacetylsalicylic acid, are given —The addition of bromine to cinnamic acid and its esters Preliminary notice J J **Sudborough** and J **Thomas**. An account of experiments made to determine the velocity of formation of the bromides of this acid and certain of its derivatives is given —The optical and magneto-optical influence of ethenoid linkings attached to contiguous carbon atoms J W **Brühl** It has been shown by Sir W H Perkin that limonene, dipentene, and $\Delta^{3\ ^{(9)}}$-*p*-menthadiene exhibit a remarkable difference in magnetic rotation, the values of the last being much higher than those of the two former The author showed that this is due to the presence of two double linkings in the position —C C C C— in the molecule of $\Delta^{3\ ^{(9)}}$-*p*-menthadiene —A difficulty in the theory of valency of W Barlow and W J Pope D L **Chapman** It is shown that the two propositions regarding the assemblages of spheres made by Messrs Barlow and Pope imply that a sphere of any size can replace any other without any resort to re-marshalling being necessary, and therefore cannot be used in their present unqualified form to demonstrate that valency is a simple volume relation —The more exact determination of the densities of crystals Earl of **Berkeley**. A conical pyknometer with thermometer stopper and graduated side-tube is used, and the evaporation of the liquid is relied on to bring the level in the capillary side-tube within the graduations The liquid used is carbon tetrachloride —A relation between the volumes of the atoms of certain compounds at the melting points and their valencies Interpretation by means of the Barlow-Pope theory G **Le Bas**. The molecular volumes of complex paraffins and alcohols can be calculated very exactly by means of the formulæ

$$\text{M V of } C_nH_{2n+2} = (6n+2)S = 6nS + 2S,$$

and

$$\text{M V of } C_nH_{2n+1}OH = (6n+4)S = 6nS + 4S,$$

where S is a constant which has an average value of 2 970, and is called the unitstere —The action of acid chlorides on thioureas A E **Dixon** and J **Hawthorne**. —3-Hydroxyphthalic and 3-methoxyphthalic acids and their derivatives W H **Bentley**, Miss R **Robinson**, and C **Weizmann** —4-Hydroxyphthalic and 4 methoxyphthalic acids W H **Bentley** and C **Weizmann** —Derivatives of naphthacenequinone W H **Bentley**, A **Friedl**, F **Thomas**, and C **Weizmann** —Dithioxanthoxalanil (preliminary note) S **Ruhemann**

PARIS

Academy of Sciences, December 31 1906 —M H Poincaré in the chair —M H Becquerel was elected vice-president for the year 1907 —Self-recording apparatus for the solar atmosphere H **Deslandres**. After giving an account of the essential conditions of the problem, the author discusses in detail the various methods possible, mentioning those already applied in different observatories It is pointed out that the more modern patterns differ both in movements and dimensions from the older forms Five diagrams accompany the paper —The observations of nebulæ made at the Paris Observatory G **Bigourdan** —A method of measuring the resistance opposed by metals to rapid deformations P **Vieille** and R **Liouville**. A law connecting the deformations of crushers used in ballistic experiments in the two cases—slow deformations, as in calibration, and deformation at varying velocities —A butyric lactone and unsymmetrical dimethyl-butylene glycol Louis **Henry** Butyrolactone, treated with magnesium methyl bromide or iodide, gives the glycol

$$(CH_3)_2(OH)—CH_2—CH_2—CH_2\,OH,$$

in about 50 per cent yield The glycol reacts with acetyl chloride, giving the chloroacetin

$$(CH_3)_2—CCl—CH_2—CH_2—CH_2Ac$$

—The conductibility accompanying the expansion of gases L **Bloch** The electrical effects due to the expansion of compressed air and oxygen are comparable, both being due to ions of fairly large mobility present in practically equal amounts The effects are very irregular, and the mean of a large number of experiments is required to obtain trustworthy results —Remarks on the thermodynamics of non-homogeneous mixtures Emil **Bose**. The Duhem-Margulès equation may be deduced in a simple manner from a formula given by Nernst for the thermal effects of the mixture of two liquids The author applies this to the case of two non-miscible liquids —A new manganese silicide G **Gin**. The new silicide has been obtained by the reduction of rhodonite in the electric furnace The composition corresponds to the constitution Si_2Mn_3 Its physical and chemical properties are described —The solubility of carbon in manganese sulphide M **Houdard**. Carbon dissolves in fused manganese sulphide in quantity proportional to the time of heating, the maximum solubility being 3 2 per cent The carbon is recovered from the ingot in the form of graphite it being indifferent whether amorphous carbon or diamond is originally added The manganese sulphide is not reduced —The density of gaseous hydrochloric acid, the atomic weight of chlorine Ph A **Guye** and G **Ter-Gazarian** An outline is given of the methods adopted for obtaining the gas in the pure state and measuring its density The mean weight of a litre of HCl at 0° C, under one atmosphere pressure, latitude 45°, at the level of the sea is 1 6398 grams The molecular weight of the gas has been calculated by the method of reduction to 8° C of the critical elements The atomic weight of chlorine thus derived is 35 461 agreeing well with the figure of Dixon and Edgar (35 463) or the value (35 460) deduced from the ratio Ag Cl for Ag (107 89) As the experiments are preliminary, the authors do not wish to lay too much stress on the exactitude of the coincidence —The melting points of the homologous hydrocarbons of the methane series D E **Tsakalotos** An empirical formula is given by means of which the melting points of the hydrocarbons between $C_{16}H_{34}$ and $C_{60}H_{122}$ have been calculated The agreement between the figures thus calculated and those actually observed is, with one exception, very close, the deviations being less than the experimental error —The study of the influence of radicals on the character of the complementary valencies of oxygen M **Tchelinzef** An experimental study of the thermal changes which take place on the addition of one or two molecules of ether to various organomagnesium compounds in benzene solution —The condensation of hydrazines with acetylenic nitriles A general method for the synthesis of the pyrazolonimines Ch **Moureu** and I **Lazennec** Hydrazines combine directly with acetylenic nitriles, and it is shown that the resulting compound is cyclic most probably a pyrazolonimine The reaction is general, and several examples are given of its application The transposition o hydrobenzoin study of the alkylhydrobenzoins and s e trisubstituted aromatic glycols MM **Tiffeneau** an **lorloncourt**.—The disease causing bitterness in wines **Trillat**. Evidence is given in support of the view th he bitterness in wine is due to the presence of an a yde resin —The cultural changes brought about in t oers of Solanum Edouard **Heckel** An account of the effects produced on several wild species of Solanum by excessive manuring —Some attempts at grafting in the Solanaceæ Ed **Griffon** In the experiments described grafting has had no specific morphological influence on either the graft or the plant —The production of a new variety of maize by traumatism L **Blaringhem** Mutilation constitutes a very powerful means for determining sudden variations, both hereditary and progressive in plants —Researches on the cultivation of asparagus in the Auxerrois Eug **Rousseaux** and Ch **Brioux** The existence of lymphoid formations producing blood cor-

pustles in the Gammaridæ L **Bruntz** —A new antelope from Central Africa, *Cephalophus leopoldi* Maurice **de Rothschild** and Henri **Neuville** —The influence of a small quantity of the radium emanation on the development and metamorphosis of batrachians P **Wintrebert**. —A comparison of sleep during the day and night N **Vaschide** Sleep during the daytime is in all cases less profound less restful, and less refreshing than sleep during the night —The treatment of malignant pustule by iodine A I **Llobet**.—The *charriage* of the northern slopes of the Pyrenees between the valley of Ariège and Roussillon' Léon **Bertrand** --Some early experiments of M Daubrée and of M de Chancourtois relative to the artificial imitation of mountain chains Stanislas **Meunier**

SOCIAL PROBLEMS IN AMERICA

The Future in America—a Search after Realities By H G Wells Pp 359 (London Chapman and Hall, Ltd) Price 10s 6d net

WE opened this book fearing that like other books by the same author it was an attempt to extrapolate or foretell the future from a mere man's quite inadequate knowledge of the present and the past, but we have been delightfully disappointed Mr Wells is acute in observation he is well informed on English social problems and he reasons carefully His visit to America was very short but it was preceded by much reading He nowhere speaks dogmatically, he evidently restrains his inclination to draw general conclusions from a sense that he may be neglecting important premises and such conclusions as he comes to seem to us to be sound and of value

Americans have never been tolerant of outside criticism even when it was obviously honest and good yet surely it is needed and is found useful by other nations Never was an outside critic more kindly and sympathetic than Mr Wells and we have no doubt that during the next twenty years this book will be referred to and quoted from by every good writer on social problems which after all are not peculiar to America The American people are like the middle classes of England France and Germany there is no feudal or aristocratic upper class there is no earth tied peasant The American idea is the middle-class idea everywhere but in America it has been carried out without restrictions it fosters that kind of individuality which thrives on open and undisciplined competition for wealth

And the time is coming when the American formula will no longer suffice Settled conditions and great possibilities of wealth given by nature to a large middle class kind of population have produced their natural effects The compound interest law of increase of wealth is in action and gigantic fortunes in the hands of quite common men have not only destroyed the idea of equality but have become a danger to the community Every energetic worker feels that there are limitations now being put to his chances of getting on It is possible quite legally for rich individuals to further their schemes by widespread corruption Corruption everywhere but especially in municipal governments has assumed such large dimensions that it seems impossible to remedy the evil The average man attends to his own personal affairs and has no sense of his duties as a citizen He resents all Government interference Indeed it is part of the American formula that the cultured and rich men and one may say the best men take no interest in Imperial or State or municipal affairs—to touch pitch is to be defiled—and that the ordinary citizen thinks only of his own interests in this world and the next Immigration is no longer British and Teutonic The German and Russian Jew, the lower classes from Austria and Italy and Turkey are—nearly one million of them a year welcomed as necessary recruits in the serf army of the capitalists In this serf army the children and women are the chief sufferers No story told of an old Lancashire factory can compete with some of the horrors of New Jersey at the present time

There has always been in America a widespread contempt not for the law but for abstract justice so that even well minded influential people do not set themselves to remedy obvious wrong when by so doing they might hurt themselves or their party in the eyes of multitudes of base and busy greedy and childish malevolent and ignorant voters The unfairness of the southerner to the negro is no longer confined to the south and the crimes of a few negroes exasperate white people so much that they forget the kindly ways of the average man of colour and thus the negro question is becoming more complex

But thoughtful Americans are already feeling the inadequacy of their old formulas New ideas are organising themselves out of the little limited efforts of innumerable men Many universities are busy on the study of social problems The younger generation is already raising an opposition to the tyranny of mere industrialism by cultivating religious philosophic literary scientific artistic and political thought and they are doing this not as a mere matter of taste but in their sacred duty as citizens

One of the most interesting chapters in this book is entitled Culture If it were possible to get Boston to read anything of recent date the perusal of this chapter would produce a much needed revolution there Between that Scylla the fervid ignorance of the workers of Paterson and that Charybdis the prestige and mere knowledge and genteel aloofness and culture which make Boston useless the creative minds of the university reformers must steer their dangerous way At futile Washington Mr Wells found a real man the anxious perplexed President who is a microcosm of his hundred million subjects who sees all that is wrong and the difficulty of reform Mr Roosevelt assimilates all that makes for reform in contemporary thought and causes it to reverberate over the land so that it becomes familiar to all people At the root of all reform is political reform creating a legislature at Washington and an executive which shall be in harmony with one another and which under proper safeguards shall be able to put aside the present obstruction of the various States Only a great educated and sustained agitation can bring about such a revolution

Mr Wells would almost leave us still in doubt may not America after all be a great futility But just at the very end we find him optimistic We are inclined to think that Mr Wells pays too much attention to America of the present and that if he thought more of America of the past he would be altogether optimistic Mrs Trollope and Cooper and Dickens differed but little in opinion and can any candid student of their writings deny that America

it is surmounted social difficulties which looked almost insuperable sixty years ago? What Mr Wells says is all true, but there is also much more to be said The average American neglects politics and selfishly thinks of his own interests, yes, but every now and again he shows himself capable of the highest kind of self-sacrifice At the back of the futile Boston culture is the spirit of Charleston Neck and Bunker's Hill, and the cultured Bostonian had this great merit, he saw that Abraham Lincoln could save the country We consider that the worst thing in America is Philistinism, commonness or vulgarity of thought, the great merit of Boston is that she has always combated this Then, as to immigration, we believe that an intermixture of all the European races (and, if we could only get it, an assimilation of the Jews) would produce the very finest nation ever known These lower races of whom Mr Wells speaks are a danger only for a time, in the second and later generations their presence will be shown in a better appreciation of music and literature and painting

The supreme danger to any State lies in the diminution of its middle class, this is the greatest lesson of history We see no chance of such a diminution in America for a very long time to come Furthermore, there is an evident growing determination in this middle class that social problems shall be solved at whatever cost Lynching is altogether evil, but it occurs only in certain parts of a country of enormous size still nearly empty of inhabitants, it certainly is altogether against the spirit of the American people, one of whose strongest characteristics has always been a respect for *law* It was a product of the slave system, and is diminishing

The Europeanised American who scorns politics is truly a curse to himself and his own country and to Europe, but there is now a new revelation Mr Roosevelt is not the only rich, educated American who has conquered his fear of touching pitch We agree with Mr Wells as to the inferiority of American school education, the root of all evils, but the sole cause of this is poor payment for teachers, and, like many another great mischief in America may be altered almost by the stroke of a pen Has not universal spitting, the habit most dreaded by Dickens, disappeared in one half-year? Anything in the way of quick reform is possible in a country like America, where everybody reads, and where the cheapest monthly magazines, published by millions, contain serious articles about the great American problems and reforms, where in all States north of the Washington parallel the people resemble the Scotch, that is, even the commonest labourers are accustomed to abstract reasoning because of their early religious education We cannot doubt that it will work out triumphantly its own and our salvation, for it is to be remembered that all the insoluble-looking problems of America are coming for solution more slowly upon England and France and Germany We believe that Mr Wells has done something important towards solving such problems, and it is not merely America that ought to be grateful to him

JOHN PERRY

NAVAL CHEMISTRY.

Service Chemistry a Short Manual of Chemistry and its Applications in the Naval and Military Services. By Vivian B. Lewes and J S. S. Brame. Third and revised edition Pp. xvi+678 (London: Henry Glaisher, Greenwich J. Glaisher, 1906.)

THIS book was primarily designed for the use of officers passing through the Royal Naval College, Greenwich, who while requiring to know something of the practical applications of chemistry to their profession if they are to carry out its multifarious duties intelligently and efficiently, have only a very limited amount of time to give to the study of the science The naval officer nowadays is confronted with conditions which were absolutely unknown to and undreamt of by those who were placed in charge of our old "wooden walls" Steam and steel and high explosives have completely revolutionised the navies of to-day, and modern men-of-war are the embodiment of the most advanced developments of mechanical, physical, and chemical science He who would handle these costly creations to the best advantage needs to have acquaintance with the scientific principles upon which their construction, maintenance, and effective employment depend, and what intelligent handling means, and what momentous issues may depend upon it was demonstrated in a manner which profoundly impressed the whole world in the ever-memorable battle of the Sea of Japan That object-lesson has given rise to much heart searching on the part of every maritime Power Whether we are bettering the example of our Eastern ally—whether, indeed, we are really following it—is a matter which gravely concerns this nation It would, of course, be out of place in this connection to discuss the various factors upon which the astonishing success of Japan depended, patriotism, courage, the spirit of self-sacrifice, discipline, intelligence, and integrity—in a word, what we understand by *moral*—were no doubt at the bottom of it all But these qualities alone might have availed little unless supplemented by skilful direction of the machinery and appliances of which our modern engines of destruction are built up, and skilful direction depends upon an intelligent appreciation of the scientific principles underlying the construction and efficient use of these appliances The rulers of rejuvenated Japan had clearly grasped this fact, and it cannot be questioned that it is to the manner in which they have given practical effect to this recognition in the training of their naval and military leaders, even during the short space of a generation, that their supremacy in the East is mainly due.

There is, of course, much in chemistry which in no conceivable circumstances can have the slightest professional interest to the naval man, and which, therefore, it would be useless and a waste of time to trouble him with

But every naval officer is the better for knowing something, for example, of the causes of corrosion and fouling of ships, of the nature of boiler incrustations, of the properties and composition of various forms of fuel; of the chemical characters of explosives,

&c., and it is precisely to matters like these that Prof Lewes's scheme of instruction is mainly directed How to develop such a scheme on scientific lines under the conditions and limitations which have necessarily been imposed upon the authors is a problem of no small difficulty That they have completely solved it in this book, even in the amended and extended form in which it now appears, they themselves would doubtless be the first to question At the same time, there is nothing in our language even approximately resembling it, and it still remains the only manual which deals exclusively with the chemistry of the special matters with which the naval officer is more immediately concerned

The present volume differs from its predecessors in many important points With the collaboration of Mr. Brame it has been largely re-arranged and in great part re-written, and care has been taken to embody the latest information so far as this was available to the authors

The theoretical part is necessarily very restricted Indeed, it is obvious that the philosophical aspects of chemistry have hardly more attraction for the authors than they have for the special class to whom the book is addressed This, of course, is one of the difficulties of the problem It is of no practical use to teach chemistry to naval officers as if they were going to be professional chemists, and the authors have therefore wisely confined themselves in the main to such theoretical aspects of the science as are related to the matters with which naval men are directly interested.

Naturally the applications of theory are constantly extending, and what is "theory" to-day becomes "practice" to-morrow—a truism of which the authors, it must be added, are not unmindful, for imperfect and partial as their treatment of doctrinal questions may be, it is probably sufficient for such developments as are likely, at all events in the near future, to occur

In one respect the book differs very materially from the ordinary run of chemical text-books, namely, in the large amount of original information it conveys Prof Lewes's official connection with the Admiralty has necessarily caused him to pay special attention to chemical matters of importance to the service, and many of the results of his inquiries, some of which, indeed, are the outcome of prolonged investigation, are summarised in his manual. Although, as stated, it is primarily intended for the naval officer, there is much in the work which is of equal interest to the military man and to the practical engineer

We have noticed one or two errors, but they are of minor importance Silicon was first isolated by Berzelius in 1823, and not, as stated, by Davy in 1813. There is no such thing as P_2O_3, phosphorous oxide has the formula P_4O_6, just as its analogue arsenious oxide has the formula As_4O_6 The description of the mode of manufacture of the lucifer match hardly corresponds with modern practice, white phosphorus is rarely used in the "strike-anywhere" match to-day; it has been almost wholly replaced by phosphorus sesquisulphide

FORMATION OF ICE ON THE ST LAWRENCE.

Ice Formation, with Special Reference to Anchor-ice and Frazil By Howard T Barnes Pp. x+260 (New York John Wiley and Sons, London: Chapman and Hall, Ltd.) Price 12s 6d net

THE effects of the severe Canadian winters on such a large river, with a variable flow, as the St Lawrence afford remarkable opportunities for studying the phenomena of ice formation, which the author has availed himself of during the last ten years, and this book records the results of his observations and the conclusions he has drawn from them Moreover, in order to render the account of his investigations on ice formation more complete, he has introduced the subject with three chapters, on the "Physical Laws governing the Transfer of Heat," "Physical Constants of Ice," and "Formation and Structure of Ice," and has added towards the end a chapter on previous "Theories to account for Frazil and Anchor-ice," which would more suitably have preceded the exposition of his own views in the fourth chapter Lastly, in the final chapter, the author gives a practical application to his investigations by indicating the causes which, in severe winters, are liable to occasion the stoppage of water-power works, and suggesting measures by which accumulations of ice at critical points, tending to arrest the flow of water, may be reduced

Three forms of ice are found in the St Lawrence in winter, namely, sheet- or surface-ice, frazil-ice, and anchor-ice, differing in their mode of formation, their general appearance, the position they occupy in the river, and the effects which they produce Sheet-ice is the well-known form of ice which, when the temperature falls below the freezing point, gradually forms on the surface at the sides of a sheet of still water, spreads out into deeper water if the cold continues, and increases slowly in thickness Frazil-ice is the French-Canadian term signifying cinder-ice, for a peculiar spiky form of ice supposed to resemble cinders, which is formed on the surface in open channels where the current is too rapid for the border-ice to extend across them, and this ice which is sometimes called slush-ice varies in its formation according to the amount of agitation of the water, appearing as flat plates on the smooth surface of a current, or as numberless minute needles in rapids and at the base of waterfalls These needles of ice increase in bulk in traversing open water for some distance, and eventually fill up the open channel during the prevalence of great cold and strong winds often experienced in Canadian winters This fine ice is often carried by the current a long way under surface-ice which has formed lower down, and, becoming attached to the under-side of this sheet, and gradually accumulating and becoming consolidated, it is liable to dam up the channel completely down to observed depths of 80 feet, and, consequently, raise the level of the river considerably above

Anchor-ice, as it is called in Canada, and known as *glace-du-fond* in France and *Grundeis* in Germany, has been long observed in most countries where ice

forms in rivers, and is the term applied to ice formed on and attached to the bottom of rivers. This anchor-ice is only formed in rivers where the current is too swift for surface-ice to form, and not in depths exceeding 40 feet to 45 feet, though in the clear sea-water off the coast of Newfoundland it is largely formed at depths of 60 feet to 70 feet. Its formation appears to be rightly attributed to loss of heat in the bed of the river from radiation, for it occurs on clear, cold nights, and is impeded by any form of shelter interfering with radiation, such as under a bridge, it does not form at all under surface-ice arresting radiation, and is less below a turbulent river than in a clear, still sea. Frazil-ice is the cause of the packing up of the ice and of the floods of the St. Lawrence, and also of the obstruction to the working of the power plants in the winter. When a river is completely frozen over, the channel is protected from the formation of frazil-ice or anchor-ice, unless there is an expanse of open water above, from which frazil-ice, and in mild weather anchor-ice, is carried down. To prevent the stoppage of the power works in the latter case, the author suggests that the gates, the rack for arresting débris, and the wheels should be placed under shelter, that the iron bars of the rack should be heated, and that the passage of the frazil-ice should be facilitated as much as possible, and prevented from agglomerating by the occasional injection of steam.

ROMANTIC INDIA

Under the Sun. Impressions of Indian Cities. By P. Landon. Pp. xii+288, illustrated. (London: Hurst and Blackett, Ltd., 1906.) Price 12s. 6d. net.

THIS is one of the crop of books on India by Press correspondents who visited the great Eastern dependency during the recent tour of the Prince of Wales. Its author had previously on one or two occasions spent some weeks in the country, and now presents part of his already published letters "recast in a more permanent form." It is perhaps inevitable that the great bulk of the impressionist literature on the East should issue from the hurried pens of the cold-weather globe-trotters, whose "butterfly zigzags" over the country undoubtedly enable them often to see things from fresh and comparative, if somewhat superficial, standpoints. With all India to roam over, it would be surprising did the oft told tale of Indian cities not bear some repetition at the hands of such an imaginative journalist as Mr. Landon. He certainly has produced a readable book, though many of his sketches convey less clear-cut impressions of the places than those of some other writers who have gone over the ground before, Steevens, for instance, and they lack proportion. Some point is seized on and overstrained with a discursiveness that causes the reader at times to lose the thread of the narrative, whilst other more characteristic features of the picture are omitted.

The author betrays a weakness for unnecessarily dragging in vernacular names (some of which are misspelt, *e.g.* "bebel," which occurs a dozen times for "bābul," the *Acacia arabica*), with no word of explanation to the reader as to what the thing is, and his too frequent use of superlatives leads him into meeting the most transcendental thing "on earth" many times on his trip. Thus we are told within a hundred pages that at Udaipur "one room is without rival on earth." The Indian antelope and cheetah are "two of the fastest animals on earth—the cheetah is beyond all question the swiftest." Jaipur has "colours that only Mandalay of all places in the world can hope to rival." A "dishonest and fugitive jeweller from France" is "the first decorator of all known periods." The Delhi grand trunk-road is "the most historic highway in the East." Although the Taj is "the crown and goal of all that India has of beauty and romance," the Queen's monastery at Mandalay is "the most picturesque place in the East, probably in the world," though a few pages previously we read that the Shwe Dagon pagoda at Rangoon also is "the most picturesque place in all the East."

As to details, he is not over careful; he speaks of bread-fruit "palms," and of the reedy banks of Calcutta "flaming with patches of rose lotus"—this might be the case if lotuses grew on banks, but they do not. At Darjiling, he says, "the valley stretches out ten miles wide from the foot of the precipice"; as a fact, the valleys there are narrow ravines, none of which has a width of more than a quarter of a mile at its bottom. The photographs of the hackneyed views one has so often seen before are good and well reproduced; the same, however, cannot be said for the coloured prints, which are unpleasantly low-toned from a too liberal application of dull paint; the sombre view of "the sunset glories of the Hugli" is utterly unlike what it is meant to represent.

A chapter is added on the later life of the notorious rebel and fugitive of Mutiny days, Nana Sahib, purporting to give "historical facts here presented for the first time." No one, however, can seriously be expected to accept as evidence the old re-discovered bazaar rumours picked up by a passing traveller and set down without absolutely any proof whatever in support of them, all the more so as such an experienced Anglo-Indian magistrate as Sir Dennis Fitzpatrick, commanding the resources of the Imperial secret police, was specially deputed to sift such rumours at the time, and finally rejected them as wholly unfounded. There is no index, but this, perhaps, is unnecessary for fugitive sketches.

OUR BOOK SHELF

Species and Varieties. Their Origin by Mutation. Lectures delivered at the University of California. Second Edition, Corrected and Revised. By H. De Vries, edited by D. T. MacDougal. Pp. xviii+847. (Chicago: Open Court Publishing Co.; London: Kegan Paul and Co., Ltd., 1906.)

IT is not surprising that the first edition of De Vries's lectures in America should be followed by a second after the lapse of a year. All the misprints that we pointed out in our review of the first edition have been corrected, and even our suggestion that uniformity in the termination of the adjectives derived from such terms as physiology was

desirable has been adopted But, curiously enough, the uniformity is intra-verbal and not inter-verbal, for whilst the physiologics and physiologicals of the first edition appear as physiologics in the second, and whilst the same course has been followed with the adjectival forms of morphology and palæontology, the empirics and empiricals of the first edition appear as empiricals in the second We condemn the manner in which this uniformity has been introduced We are perfectly aware that morphologic is correct, and that morphological is hybrid and redundant, containing as it does a Greek and a Latin adjectival termination, but we hold that the former is ugly and that the latter is not If the customary termination is allowed in the case of empirical, on what grounds is it refused in that of physiological? If in our choice of the forms of terms we have to choose between those with the meaning and sound of which we have become familiar, be they never so hybrid, and those forms of them that we are told are strictly logic, let us by all means choose the former

There is no need to commend the book It is indispensable, inasmuch as it is the only available account of Prof de Vries's work in English, so far

A D D

Time and Clocks a Description of Ancient and Modern Methods of Measuring Time By H H Cunynghame, C B Pp 200 (London Archibald Constable and Co, Ltd, 1906) Price 6s net

IN this volume the author has gone much further than the title and subtitle would lead one to expect Not only are the "ancient and modern methods of measuring time" discussed, but an attempt has been made to lead the non-scientific reader to a knowledge of the many principles involved in a series of logical steps Mass, gravity, space, harmonic motion, &c, &c, are all discussed at length, whilst excursions into the ancient concepts of various phenomena are by no means infrequent

We rather fear that the reader who has not gone through a course of dynamics will find it hard to grasp the significance of the various discussions, despite the clear reasoning and simple examples, whilst to the science student a greater part of the matter is unnecessary

Still, in the hands of a youth trained in the ideal fashion suggested by the author at the end of the book (p 186), the volume, carefully digested should prove of service and tend "to keep the young rascal from worrying his sisters and stoning the cat"

W E R

Conduction of Electricity through Gases By Prof J J Thomson, F R S Second edition Cambridge Physical Series Pp vi+678 (Cambridge University Press, 1906) Price 16s

THIS book, the first edition of which was fully noticed in NATURE (vol lxix, p 74), will be welcomed by all those who are striving to keep up with the rapidly growing literature of an increasingly important subject It was the author's researches in this field which first paved the way for the rapid extension of our knowledge which has taken place in the last few years Much still remains to be done before the innumerable phenomena encountered in the study of the electrical behaviour of gases can be considered fully elucidated, and to the thoughtful worker these still unoccupied regions will probably be the most attractive While this book has been waiting notice on the reviewer's table, frequent reference has been made to it for work that has appeared since the issue of the first edition, and in no case in vain It maintains in an enhanced degree its good qualities as a work of reference none engaged in the subject can be without, and as an authoritative exposition of a field of work the author has made his own it has its own place among a wide circle of readers.

The New Physics and Chemistry a Series of Popular Essays on Physical and Chemical Subjects By W A Shenstone, F R S Pp vii+360 (London Smith, Elder and Co, 1906) Price 7s 6d net

WHEN a collection of essays upon the chief problems in physical science engaging the attention of investigators at the present time is published without an index, its value to students of scientific progress is greatly diminished Mr Shenstone evidently does not intend the book to be used for reference, otherwise he would have provided a key to its contents His essays, which originally appeared in the *Cornhill Magazine*, represent popular science at its best, and rehearse the outstanding features of the new physics and chemistry in a style easy of comprehension The book should serve a useful purpose in revealing to readers familiar with the concepts of physical science the richness of fact and theory relating to the properties and constitution of matter and the ether

The Manufacture of Light By Prof Silvanus P Thompson, F R S Pp vi+67 (London Macmillan and Co, Ltd, 1906) Price 1s net

PROF THOMPSON'S evening lecture delivered at the York meeting of the British Association in August last is here presented in an attractive form Twenty-eight clearly reproduced illustrations assist greatly in a thorough comprehension of the discourse After a brief description of primitive sources of light and a reference to the inventions of gas and electric lighting the general question of incandescence is discussed This is followed by an account of photometry and an explanation of the inequality in different directions of the light from various sources After dealing with the sensitiveness of the eye to radiations of particular wave-lengths, the measurement of emission, and the temperature and quality of radiation, Prof Thompson describes various incandescent gas-lights, new kinds of glow-lamps and arc-lamps, and concludes with a consideration of the cost of the manufacture of light The little book should have a wide popularity

Lichtstrahlung und Beleuchtung By Paul Hogner Pp ix+66, illustrated No 8 of Dr G Benischke's "Elektrotechnik in Einzel-Darstellungen" (Brunswick Vieweg and Son, 1906) Price 3 marks

THIS book gives a clear exposition of illumination by means of electric arc lamps The theory of the subject is well set forth and starts from a sufficiently elementary foundation to be easily followed by the average student The chief feature of the work is a number of tables giving data concerning illumination under different conditions and these might be profitably consulted by those wishing to arrive at the best results in a given case The book is well printed and the diagrams are good

A Synonymic Catalogue of Orthoptera Vol ii, Orthoptera Saltatoria, Part i (Achetidæ et Phasgonuridæ) By W F Kirby (London Printed by Order of the Trustees of the British Museum, 1906) Price 15s

THIS volume is the continuation of Mr Kirby's synonymic catalogue the first part of which was published in November, 1904 The present work includes the Achetidæ, or crickets, and the Phasgonuridæ or long-horned grasshoppers, often improperly called Locustidæ The true Locustidæ or short-horned grasshoppers—often called Acrididæ—will form the third and concluding volume of this work

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Production of Radium from Actinium

IN a recent letter to this Journal (November 15, 1906) Dr. Boltwood has given an account of experiments which show that radium is continuously produced in a solution of actinium, and concludes that radium is a disintegration product of actinium, the latter occupying an intermediate position in the family of disintegration products between uranium and radium. The radium is produced from the actinium at about the theoretical rate, and he deduces in a simple way that the time for radium to be half transformed is about 3000 years. These results of Dr. Boltwood are of great interest, and mark an important stage in the search for the somewhat elusive parent of radium.

It may be of interest to the readers of NATURE to give a brief account of some experiments I have made on this subject, the results of which were communicated to the American Physical Society at New York on December 28, 1906. In the Bakerian lecture of 1904 (Phil. Trans., A, p. 169, 1904) I briefly described some experiments that had been commenced to see whether actinium produced radium. Some of Giesel's actinium was taken, dissolved in acid, and the greater part of the radium then present was removed by precipitating barium in the solution. The amount of radium left in the solution was determined by the emanation method, using an electroscope carefully calibrated by means of a standard radium solution. Over a period of three months no very certain evidence was obtained that the amount of radium had increased. The solution of actinium was then set aside in a closed vessel with the intention of testing it for the presence of radium at regular intervals. In the meantime, the great danger of possible contamination, in testing solutions for radium in a laboratory where considerable quantities of radium were continually in use, was recognised, and for this and other reasons the solution was not again tested until two and a half years had elapsed.

When Dr. Boltwood informed me of the growth of radium in his actinium, I at once tested this solution for radium by the emanation method. A preliminary observation showed that there had been a large increase in the quantity of radium in the solution in the interval since the early experiments. In the course of making an accurate determination, the solution was unfortunately contaminated with radium, probably through the use of a lubricant on a stop-cock attached to the vessel. Under such conditions I could place no reliance on the final measurement. Happily, however, I had placed aside, at the time of preparing the original actinium solution, a sample of the actinium salt the radium content of which at that time had been accurately determined. This was now tested, and the amount of radium in it was found to have increased at least four times the initial value in the two and a half years' interval, showing a rate of growth of radium in the actinium of much the same magnitude as that observed in the experiments recorded later. I think that my failure to observe an increase in the amount of radium in the actinium solution over a period of three months was due to the unsuitable chemical treatment used initially to remove the radium from the actinium. An excess of sulphuric acid must have remained in the solution, and this would tend to precipitate the radium when formed as sulphate—a condition in which probably only a fraction of the emanation would be released. A considerable increase in the amount of radium might consequently only show a small increase in the amount of emanation carried away by aspirating air through the solution.

Experiments were at once undertaken to remove the radium again from the contaminated solution by a simpler and better method. This proved successful, and only a minute fraction of the radium was left in the solution. The latter was then placed in a glass vessel, and the amount of radium in it determined weekly by boiling out the emanation, and then introducing it into a suitable emanation electroscope. A progressive increase in the amount of radium has been observed, amounting to 80 per cent. of the initial value over a period of five weeks. If this rate of growth continues at a constant rate, the amount of radium in the solution at the end of a year should be more than eight times the initial value. The actinium used in this experiment was equivalent to about half a gram of an actinium preparation of activity about 250 times uranium, and the rate of growth of radium observed corresponds to about 3×10^{-9} gram of radium per year.

There is one important point that suggests itself in considering the results as given by Dr. Boltwood. The growth of radium observed in his actinium solution possibly might arise, not from the actinium itself, but from another distinct substance, normally separated from the radioactive mineral with the actinium. In order to throw some light on this question, I compared the rate of production of radium observed in my actinium with the rate of production to be expected on the simple theory, supposing that the actinium is transformed directly into radium. Without going into details, it suffices to say that this can be done by comparing the α-ray activity of a known fraction of the actinium solution in the form of a very thin film with that of a thin film containing a known quantity of radium. In this way I calculated that the growth of radium observed agreed with the disintegration theory, if the period of half transformation of radium was about 2600 years. The period so deduced is not very different from that determined by Boltwood from quite distinct considerations. This is satisfactory so far as it goes, but such an agreement between the periods obtained by the two methods implies that the activity, due to the actinium in pitchblende, is about the same as that due to radium and its products. As a result of careful measurements, Boltwood, however, found that this is not the case, for the activity due to the actinium is only a small fraction of that due to radium. Further experiments are required to explain this anomaly.

There is one other point on which I have made a number of experiments. If radium arises from actinium, it should be produced by the active deposit of actinium which contains the last products of the actinium series, namely, actinium A and B. In order to test this, a platinum plate was made the negative electrode in a vessel containing a very active actinium preparation, and the active deposit was collected for a week or more. The platinum plate was then removed and immersed in a closed vessel containing dilute hydrochloric acid. After standing for a week, the accumulated emanation was boiled out, and the amount determined in an electroscope. Knowing the amount of the α-ray activity due to the active deposit on the platinum plate compared with the activity due to a thin film of radium, and also the time of exposure, it is a simple matter to calculate the growth of radium to be expected on the assumption that radium is half transformed in about 3000 years. Using a small platinum plate, the amount of radium observed was certainly not greater than one-tenth the theoretical amount, and, with a much larger plate not more than one-fifth. In these experiments the greatest care was taken to avoid any possible radium contamination. The observations were made in the chemistry building which is free from radio-active material, and I was fortunate in having the use of the emanation electroscopes of low natural leak, set up by Mr. Eve, who kindly assisted me in these experiments. The plates and solutions employed were initially tested for the presence of radium, so that the growth of radium observed, though much smaller than the theoretical amount, was still quite definite. These experiments are being continued. The smallness of the amount of radium observed may either be due to the presence of another change between actinium B and radium, or, what is more probable, to the loss in an electric field of the radium formed on the platinum plate. Such a possibility is suggested by the results of Meyer and Schweidler, who observed that there was always a small residual activity on substances, exposed for a long time in the presence of the actinium emanation, which gradually disappeared.

Further experiments are in progress to examine in the early stages the growth of radium in actinium, initially freed from radio-actinium and all its products If actinium changes directly into radium, the initial growth of the radium should be much smaller than that to be obtained three months later, when the products are in approximate equilibrium.

The results of my experiments are thus substantially in agreement with those of Dr. Boltwood There is no doubt that the immediate parent of radium is present in actinium separated from pitchblende, but certain points remain to be settled before it is definitely proved that radium is the direct lineal descendant of actinium Since the proof of this relationship between actinium and radium involves many important theoretical consequences, I think it is advisable to await the results of further experiment in this direction before basing far-reaching conclusions upon it.

E RUTHERFORD

McGill University, Montreal, January 3

Helium and Argon in Common Rocks

THE quantity of radium found in granites and kindred rocks (Proc Roy Soc, A, vol lxxvii p 472), about 10^{-11} grams per c c, suggested that the associated helium might be present in sufficient quantity for spectroscopic detection This has proved to be the case Thus 250 grams of Matopo granite yielded 3 c c of nitrogen on heating This nitrogen, on sparking down, gave a residue of about 1/100th part of its own volume The residue was introduced into a vacuum tube, and showed the spectra of argon and helium quite brilliantly, and in about equal intensity Similar results were obtained with syenite rocks from Mt Sorrel in Leicestershire, and from Norway

It seems more than probable that these observations afford an explanation of the nature of the gases evolved by mineral springs The invariable presence of a notable quantity of helium in such gases has always been considered remarkable It would seem that it may be sufficiently explained by the action of hot water in disintegrating common rocks and liberating the gases contained

It is my intention to examine a large selection of common rocks and minerals, and particularly with the view of determining whether helium in them is always associated with radium, or whether its presence can ever be attributed to radio-activity of ordinary materials

R J STRUTT

Sunnyside, Cambridge, January 13

Ionisation and Absorption and Anomalous Dispersion

DR STARK (NATURE, vol lxxiii, pp 78, 389, 533) has given a theory, based on his canal-ray experiments, according to which spectrum series are due to positive ions It occurred to me that its applicability to thermal emission might be tested by experiments on the ionisation accompanying the anomalous dispersion in sodium vapour Accordingly, together with Mr Needham, I made some preliminary experiments, using a slight modification of Prof Wood's well-known apparatus ("Physical Optics," p 340), of which the results seem to be of sufficient interest to deserve publication

We used a steel tube, 40 cm long, with an insulated iron wire stretched inside and along it about 1 cm from the sodium surface The poles of a battery were connected to the wire and tube through a liquid resistance and galvanometer (1 division $= 10^{-8}$ ampere about), the tube was placed between the collimator and grating of a spectroscope, and the image of a horizontal fine wire stretched across the slit was observed in the first spectrum with a micrometer eye-piece The separation, due to anomalous dispersion, of the two halves of the image on opposite sides of the absorption band was assumed to be a sufficient measure of the anomalous dispersion.

Curves constructed from observations of anomalous dispersion and current show that every variation of the ionisation, due to some irregularity of pressure and temperature, is accompanied by a corresponding variation in the anomalous dispersion

The simplest explanation of the parallelism between the curves is that the D lines of sodium are due to positive ions rather than to neutral atoms, in accordance with Stark's theory

THE MILLAIS BRITISH MAMMALS [1]

WITH the appearance of this volume we have the pleasure of congratulating the author on the completion of a very heavy task As we have had occasion to remark in our notices of the two earlier volumes, from the point of view of pictorial illustration the work is in the main all that can be desired, and there is little doubt that in this respect it will long remain absolutely without a rival Our very heartiest congratulations may accordingly be tendered to Mr Millais and his fellow artists on the result of their endeavours to illustrate in an adequate and exhaustive manner the living and recently exterminated mammals of the British Isles In giving as the

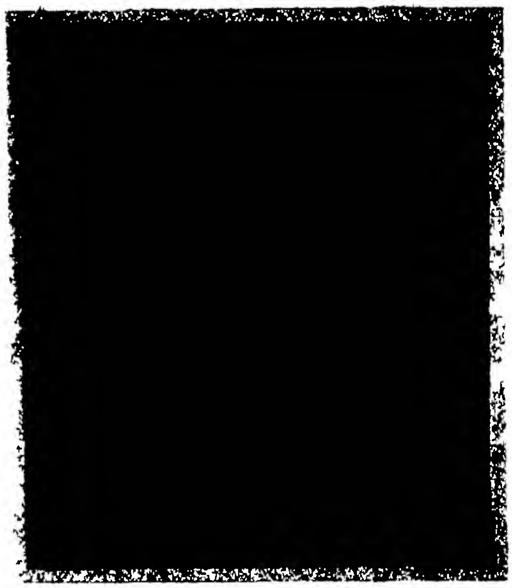

FIG 1—The Hare. From The Mammals of Great Britain and Ireland

frontispiece of the present volume a picture of a southern right-whale attacked by a party of grampuses, or killers, it may possibly be objected that the author has introduced a scene which cannot now be witnessed in British waters Since, however, the past as well as the present state of the fauna of our islands enters into the purview of the work, there may be justification for such an illustration, and even if this be not the case, the privileges of artistic license may be pleaded as sufficient excuse Had space been available, we should have had much pleasure in reproducing one of the full-page illustrations which form by far the most striking feature of the work Failing this, we have to be content in presenting to our readers (by the courtesy of the publishers) three of the smaller illustrations as examples of the pictorial merit of the work

The groups included in the present volume comprise the hares and rabbit, the ungulates, of which (if we exclude the white park-cattle, which are obviously not wild animals) the red deer, the fallow deer, and

[1] "The Mammals of Great Britain and Ireland By J G Millais. Vol III. Pp. xii+384, illustrated (London Longmans, Green and Co., 1906) Price 6l 6s net

the roebuck are the only survivors in a wild, or half-wild, condition, and the cetaceans

In regard to the hare, the author discusses, without coming to any very definite conclusion, the popular idea that this animal sleeps with its eyes open Without having any first-hand information to offer on the question, we venture to suggest that the idea has no foundation in fact, as it must be obvious that when an animal is unconscious it can make no use of its eyes, whether open or shut Many persons, it appears, doubt whether the rabbit can swim; but on this point Mr Millais has ample testimony, and he describes in detail the manner in which this rodent makes its way in the water on the rare occasions that it takes to that element

In "British Deer and their Horns" Mr Millais has already shown that he is well acquainted with the habits of the three surviving British representatives of the Cervidæ, and on this subject his observations in the volume before us are well worthy the best attention of the reader Of special interest is the statement that the new antlers of deer begin to grow before the old ones are shed, this, so far as we are aware, not having been previously recorded

FIG 2—Head of an English Red Deer killed in 1905 Points, 15 Generally considered to be the finest example taken within recent years From 'The Mammals of Great Britain and Ireland

In the course of his account of the red deer Mr Millais devotes a considerable amount of space to the contention that the division of this widely distributed species into local races is not supported by the evidence available "All the needless names on the part of scientific zoologists, who in most instances have worked on insufficient evidence, have," he writes, "only resulted in endless chaos, to the somewhat supercilious amusement of sportsmen, who in this case have shown that they know more about the red deer than the zoologists"

To the allegations in this statement we have no hesitation in giving a flat denial, and it is nothing short of presumption on the part of an amateur naturalist like Mr Millais to set up his opinion against those of specialists of the calibre of Prof Einar Lönnberg, of Upsala, and Dr. Satunin, of Tiflis

The plain fact of the matter (and there are occasions when it is necessary to write strongly) is that our author does not realise what naturalists mean by local races or subspecies, as may be gathered from his remarks concerning the intergradation of different local forms of red deer Is he aware, we may remark, that the essential idea of a subspecies is that it should intergrade with the typical or some other form of the species, and that many naturalists claim that when such connecting links have died out the aberrant form must rank as a species? Lack of knowledge characterises also his remarks concerning minor local differences in animals The fact that Perthshire grouse are distinguishable by an expert from the birds found in Caithness, and Tay salmon from Tweed salmon, is, for instance, no argument against the validity of subspecies On the contrary, it tends exactly the other way, merely giving rise to the question as to the degree in which it is advisable, or practicable, to recognise such local differences in zoological nomenclature

That the large, black-bellied eastern red deer or maral, and the small North African red deer are perfectly distinct from the typical red deer of Sweden does not admit of argument Dr Lonnberg, in a paper (*Arkiv Zool*, vol iii, No 9, 1906) which may have appeared too late for mention by Mr Millais, goes further than this, and separates the Norwegian red deer as *Cervus elaphus atlanticus* and the Scotch animal as *C e scoticus*, but these local forms, as might be expected, are much nearer one another than are those mentioned above

In treating of the white park-cattle, Mr Millais, we are glad to see, recognises the fact that they are essentially descendants of albino domesticated breeds, and in no sense wild animals He believes, however, that they are derived from Continental rather than British breeds In this respect he runs counter to the opinion of Low, who knew more about these cattle than many later writers, and it would seem that he is unacquainted with the white Pembroke breed, of which specimens are now living in the Duke of Bedford's park at Woburn Anyone who has seen these animals will have little doubt as to where to look for the ancestry of all breeds of park-cattle

In regard to relics of the old wild ox or aurochs Mr Millais states, on the alleged authority of the present writer, that two horns, formerly used as drinking cups, are preserved in Paris If he will refer to "Mostly Mammals" he will find it stated that, up to the French Revolution, both these horns were preserved in Alsace, and that only one, which probably did not belong to the aurochs at all, was mounted as a drinking cup Both have now disappeared so far as can be ascertained Since Mr Millais is sceptical as to the view now generally accepted with regard to the colour of the aurochs, or urus, it may be well to quote the observations on

this subject of Prof T. Noack, who, after referring to certain errors by the copyist in the German edition of Herberstain's work published in 1556 or 1557,[1] concludes as follows:—"Der *Bos primigenius* hat sich aber zweifellos in verschiedene Lokalrassen gespalten, die vielleicht auch verschieden gefärbt waren, den wir haben keinen Beweis dass alle Ure schwarz mit weissgrauem Rückenstreif waren, der auch bei dem Herberstainchen Exemplar sehr gut angedeutet ist" As the late Prof Nehring was also convinced that Herberstain's aurochs was black, it will require much more evidence than is offered in the present volume to make us believe that it was more probably red

As regards the section on British Cetacea, which occupies a large portion of the volume, we are glad to be able to accord almost unstinted praise to the author Mr Millais has seen for himself a considerable number of the species he discusses in their native waters, and he is therefore able to write with authority regarding their habits and appearance Many of his sketches and photographs are therefore of special value and interest He has, of course, much to say with regard to the recent occurrence of a number of sperm-whales in northern British waters, and as the result of these observations it may be hoped that the statement as to this species being an exclusively tropical and subtropical cetacean will in time disappear from text-books It may be added that our author appears to be in some degree of uncertainty whether the right-whales, on the one hand, and the finners and humpbacks on the other, represent families or subfamilies, since in one passage he refers to the two groups as being of subfamily rank, and yet gives their titles as Balænidæ and Balænopteridæ In referring to the horny "bonnet" and tubercles on the head of the southern right-whale, the author makes no reference to the important observations of Prof E Lonnberg in his account of the cetaceans of South Georgia, this, however, may be due to the latter having been published too late for mention

FIG 3—The Common Rorqual From "The Mammals of Great Britain and Ireland"

That the present volume and its fellows will do something to arouse greater interest among the wealthy classes (for it is not a poor man's book) in the mammals of the British Isles may be sincerely hoped In all that relates to the habits of the animals he describes, and likewise in matters connected with sport, the author, who is an energetic and enthusiastic field-naturalist may be taken, at all events in the main, as a trustworthy guide On the other hand from what has been stated above, it is evident that in matters connected with systematic zoology it will be advisable for his readers to consult the writings of trained zoologists before taking all Mr Millais has to say as gospel R L

[1] In one place Noack gives the date as 1556 and in a second as 1557

THE MATHEMATICAL TRIPOS AT CAMBRIDGE

NOT only have physicists and engineers and other men who apply mathematics been anxious for many years for reform at Cambridge, but everybody who has wished to see the study of mathematics retain its place in general education Again, nearly all who are interested in the training of those mathematicians who are expected to devote their lives to original investigation have expressed much the same anxiety The long-considered principles of a proposed large reform were brought before the Senate eight months ago in a report of the mathematics board, to which were appended twelve resolutions supported by every one of the mathematical professors and university lecturers in mathematics, and these resolutions, after they had been before the Senate five or six months, were voted upon and carried by majorities varying from 10 per cent to 40 per cent on October 25, 1906

To carry out these resolutions, regulations for the examination have been prepared, and must be approved at an early meeting, but at this late hour a force is being organised which means, not merely to oppose the regulations, but to kill all hopes of reform by reversing the recent decision of the Senate

The proposed syllabus of subjects for part I includes geometry, algebra and trigonometry, and analytical geometry with elementary work in the infinitesimal calculus, dynamics, and optics It seems to us very good, and will no doubt in time in the hands of the mathematics board become excellent Six papers will be set, each paper possibly containing questions from all parts of the syllabus The questions in the physical subjects will be of such a character as to test knowledge of the physical phenomena and their relations, and not merely an ability to deal with the analytical developments of hypotheses A large proportion of such riders as are set will consist of simple examples illustrating numerically or otherwise the corresponding theory In their answers candidates will not be restricted to the use of the methods indicated in the syllabus The most important regulations are that a student may take part I in his second term, and that the three lists of honour men shall be placed in alphabetical order

Schedule A of part II is not only an excellent course on mathematics, including elementary parts of the theory of functions and differential equations but it includes those parts of dynamics hydromechanics, astronomy, electricity and optics (we wish we could say physical optics) which give the best illustrations of the applications of the mathematical part, illustrations which must be interesting even to

those students who are likely to proceed to the highest work in pure mathematics. Schedule B comprehends the highest kind of work in all parts of pure and applied mathematics which may be expected from men of the age and experience of the best candidates.

The examination in part ii comprises the subjects in Schedules A and B. Schedule A contains the ordinary subjects to be taken by all candidates, the B subjects being taken only by men who are candidates for a mark of distinction. Six papers will be set on A and not more than six papers on B. In each of the papers on A there will be set some simple questions specially indicated, partly on the syllabus of part i., a candidate who answers these questions sufficiently well will be entitled to honours. The questions on the various subjects will be distributed among the papers at the discretion of the examiners. Some months before the examination the registrary must be furnished with names of students who intend to present themselves as candidates *for distinction* in subjects B, specifying their special subjects or branches of subjects, and still some time before the examination students will specify the range of subjects B in which they desire to be examined. It is again laid down, as in part i., that there will be tests of knowledge of phenomena in the physical questions, and simple numerical or other illustrations will be given. Also the questions on even the subjects of Schedule B will consist in part of questions of an elementary or simple character. Part ii cannot be taken earlier than in the eighth term. The list of successful candidates for honours will be in three classes, wranglers, senior optimes, and junior optimes; the names in each being in alphabetical order. The class in which a man is placed depends usually on his answers in Schedule A, but in case of doubt his answers to B may be consulted. A distinctive mark is attached to the name of a man who has done fairly well in Schedule B, and a different mark if he deserves special credit for his answers to B.

Now there is no doubt that much depends upon the spirit in which an examiner acts, he may greatly help or hurt the desires of the reformers, but surely this reform is a great step in the right direction. The old order of merit did incalculable harm. Candidates spent far too much time in the details of the general mathematical course, and as straightforward questions would have been answered equally well by all the good men, to differentiate them it was necessary to set questions which were complex and indeed tricky. Again, a just order of merit can be arranged only if all students are examined in the same subjects, and to compel all students to study the same subjects in the one way that leads to success in such an examination is uneducational. Not only has the course of study been mischievous for physicists and engineers, who ought to be allowed to advance quickly to those parts of higher mathematics which are necessary for them, but it is utterly uninteresting and hateful to the general student, for whose culture it might be made valuable. The greatest sufferer hitherto, however, has been the real mathematician, who is drilled so long on elementary work that even after he becomes a wrangler he is only ready to begin that higher work which he might have studied years before. In nineteen cases out of twenty he has become stale, so that even when he becomes a teacher of mathematics he is no longer a student. It would be useless for us to express an opinion as to the effect of the examination upon those Cambridge pure mathematicians from whom an advancement of knowledge might be expected; a senior wrangler of European reputation has given a curious opinion in NATURE, February 12, 1903, p. 339.

This reform will be far-reaching; it will extend to all places in Great Britain where a Cambridge man teaches, and to all examinations in which the Cambridge examiner has been in the habit of setting riddles and conundrums as questions. A large general committee has been formed of men who think that the regulations should be approved. It is representative of Cambridge at its best, not merely in men who teach, but in men who are doing original work in pure mathematics and mathematical physics and engineering, as well as in history and literature, scholars and workers of all kinds. It would be invidious to compare with these the names of the men who have organised the opposition. A scrutiny of the October votes shows that the members of Senate who are resident in Cambridge are in favour of reform by majorities considerably more than in the case of the general members. The opponents of reform now call upon all country members to come to Cambridge and record their votes. Should they persist in their intention, it is just possible that they may succeed in reversing the recent decision of the Senate, but if they do they are establishing a precedent which cannot conduce to the smooth and consistent working of the University.

There is another matter for these gentlemen to consider. Should they succeed, it is certain that the reformers will ask for and obtain a Parliamentary Commission. Is it likely that such a commission will inquire only into the question of mathematics? There is the Greek question, and there are others which the opponents of reform surely do not wish to have examined. Some of us wish that they would persevere and defeat the reformers, so that our greatest university might through a commission get those other reforms which it is hopeless to expect from the Senate.

JOHN PERRY.

THE INTERNATIONAL SEISMOLOGICAL ASSOCIATION

THE first meeting, since its definite organisation, of the committee of the International Seismological Association was held at Rome on October 16, 1906, and was attended by representatives of each of the States belonging to the association. The United States having quite recently joined, the only important outstanding countries at present are Great Britain and France. The answer of France has not yet been received, while Great Britain has signified its intention to join under certain conditions, among which the simultaneous adhesion of France is the only one which at present prevents our country from being a member of the association. Nevertheless, both countries sent representatives to the meeting, M. Bigourdan acting for France and Prof. Schuster for Great Britain.

The time of the meeting was taken up in great part by questions of organisation, as, for instance, the drawing up of regulations concerning the procedure of the committee itself. Prof. Palazzo, of Rome, occupied the chair, and was re-elected president until the general meeting of the association, which is to take place in September. Reports were presented from the various States showing the organisation of the seismic service in the different countries, and these reports gave evidence of the great interest now generally taken in the seismic tremors of the earth.

The more important scientific questions submitted to the conference were deferred for decision to the general meeting in the present year, but it was decided to supply the Arctic station of Disko with an instrument for measuring the vertical component of disturbances, and to open a competition for the

construction of a seismograph which shall be suitable for the measurements of tremors having their source near the place of observation. Advertisements giving details of this competition have appeared in various papers in this country (see NATURE, January 3, p. xci).

It may be remembered that an organisation for studying the propagation of earthquakes was discussed at the last meeting of the International Association of Academies held in London in 1905, and that a committee was then appointed to formulate the views of the united academies, the originally proposed scheme for the seismic organisation not having met with general approval. This committee met, and its recommendations were subsequently approved by the council of the International Association of Academies. The International Seismological Association has accepted the suggested modifications, the general tenor of which was to safeguard the internal organisation of the earthquake observations in different countries, confining the international work to those physical questions of earthquake propagation which can obviously only be dealt with on an international basis. It is to be hoped that the spirit of these modifications will be adhered to, and that no attempt will be made to encroach on the functions which more definitely concern each country separately. We are glad to note, therefore, from the proceedings of the recent conference that both the questions of a more particular study of the districts surrounding Vesuvius, which primarily concerns Italy, and the foundation of a station in Iceland, which primarily concerns Denmark, were postponed.

The social functions of the international meeting were well looked after at Rome, the members being most hospitably entertained, and also provided with tickets enabling them to travel at about half-fare over all State railways during the meeting, and for several days before and after.

SCIENCE IN HIGHER EDUCATION

IT is satisfactory to notice the attention now being given to scientific methods in education, not only by teachers and others actively engaged in educational work, but also by prominent statesmen. During the past week several important educational conferences have been held, and a report of one specially organised by science teachers appears elsewhere in this issue. But the dominating note of other conferences concerned with the school curriculum in general and subjects belonging to the literary side of education in particular is that of scientific method. Whether in the study of ancient or modern languages, in the cultivation of mental attitudes or the development of the body, it is clear that authoritative opinion considers the best methods of teaching should be based upon principles which have long been advocated by men of science. The little leaven of science is leavening the whole lump of educational effort, and the result is gratifying to contemplate.

Provided that scientific methods are adopted, that is, methods which aim at making pupils work out their own intellectual salvation, it does not matter much what subjects are studied. What we have always wished to avoid, and what we are glad to see now meets with unanimous disapproval, is instruction which is not education, the drudgery of learning phrases or performing mental gymnastics in literature, mathematics, or science without attention to the more valuable faculties of critical thought and originality. From the condition of a passive absorber of teachers' notes and the pemmican of text-books of former days, the pupil is gradually being recognised as an active agent who may be led to make his own observations and form his own conclusions, whatever the subject of study may be. It can scarcely be said at present that the old methods have disappeared from our schools and colleges—the requirements of the old universities and examining bodies prevent this end from being reached—but the feeling of practically all active thinkers and workers in the world of education is in favour of the adoption of principles with which we are completely in sympathy, and their influence is gradually giving the spirit of life to what have been the dead bones of school work.

Our statesmen, also, and in particular Mr. Haldane, Secretary of State for War and president of the British Science Guild, are taking opportunities to impress upon the nation the essential part which science and higher education must play in the polity of the modern State if progress is to be secured. We are glad, therefore, to extract from reports of speeches made last week by Mr. Haldane and Mr. Asquith some remarks expressing conviction of the value of factors which have long been recognised in these columns as essential to national welfare.

SCIENTIFIC THOUGHT

An international economic congress, arranged by the council of the Royal Economic Society, was held on January 9 and 10 at the London School of Economics. Mr. Haldane, M.P., occupied the chair during the earlier portion of the morning session on the first day as president of the society, and delivered the introductory address. Mr. Haldane is reported by the *Times* to have said:—What ever other differences there may be between the nations there is a brotherhood—a brotherhood the reality of which is asserting itself more as year succeeds year—the brotherhood of science. We are to-day recognising that in science, as well as in other things, international cooperation is essential, and perhaps in no department is that more marked than in the department which deals with the science of the State. It is not only in economics that this kind of wider outlook is beginning to come to people. In science of every kind we have witnessed the tendency of the nations to specialise. Perhaps it is more easy to preserve a common basis in those sciences which do not touch human nature, but there is one thing that is true of all sciences, and that is that their methods are necessarily abstract. Do not let us be carried away with the notion that because a method is abstract therefore it is not an indispensable method for getting at the truth. It is obvious that the chances of reaching the truth are greater in certain cases the greater the abstractness of the method.

I have at this moment two books in my mind books which in a sense are to-day out of date but which, in another sense, will never be out of date, because they are the most perfect illustrations of true scientific method—the method which does not allow itself to shut out of view facts by the narrowness of its conceptions. One is Darwin's "Origin of Species," the other is Adam Smith's "Wealth of Nations," a book written by a man who had profoundly freed his mind from every kind of narrowness.

After dealing with the value to statesmen of the study of economics Mr. Haldane spoke of the internationalism of science. He remarked:—It seems to me that this tendency to the internationalism of science, which is again after 300 or 400 years beginning to set in, which does not depend on our speaking a common language but does depend on our becoming more and more specialists working out different departments of great and complicated questions—it seems to me that this new tendency is one which should fill us with hopefulness for the future. It has been said, and said with truth, that this is not an age of great men. We do not seem to be producing a Newton or a Gauss, a Helmholtz or a Laplace with the frequency with which former generations produced these outstanding figures, and yet, on the other hand, who will doubt that the general level of science is far higher to-day than it was a generation ago, and still higher than it was a generation before that? People have realised that it is

because of the necessity of specialisation, just because of the vast amount of work which people will have to do if they are to do anything successfully, that the men of science to-day have to know a great deal more, and therefore have to specialise a great deal more, before they can work usefully for the realisation of a common purpose It is an age in which we recognise the enormous strides which science has made, the vast amount that has to be known before an individual contribution is possible It is an age in which we are coming to see more and more clearly that the man who will contribute anything, who wishes to serve his country, who wishes to serve the world, does best to confine himself to that which he is sufficiently furnished to undertake "He" wrote a great man, "who would accomplish anything in this world must learn to limit himself" and that is essentially true of science to-day

The University Spirit and Function

Mr Haldane delivered his address as Lord Rector of the University of Edinburgh on January 10 He referred at length to the function of the university in the modern State The first purpose of a nation—and especially of a modern nation—ought, he said, to be to concentrate its energies on its moral and intellectual development, and this means that because it requires leaders as the instruments of this development, it must apply itself to providing schools where leaders can be adequately trained At this point the history of the modern State shows that the university plays an important part For the production of that small body of men and women whose calling requires high talent, the university alone, or its equivalent, suffices It is the almost indispensable portal to the career of the highest and most exceptionally trained type of citizen If universities exist in sufficient numbers and strive genuinely to foster the moral and intellectual virtue the humanity which has the ethical significance that ought to be inseparable from high culture, then the State need not despair For from among men who have attained to this level there will emerge those who have that power of command which was born of penetrating insight In a university it is not merely the lecture rooms and laboratories and libraries that are important—the places where those who are busy in the pursuit of different kinds of learning meet and observe each other are hardly less so The union the debating society, the friendship of those who are struggling to maintain a high level—all these things go to the making of the scholar Certainly in the Scottish university of to-day there is no lack of either opportunity or provision for the formation of the tastes of the scholar and the habits of the worker A man may go from these surroundings to devote his life yet more completely to literature, or science, or philosophy, or he may go to seek distinction in a profession or success in commerce Whatever occupation the student chooses, he is the better the greater has been his contact with the true spirit of the university The university training cannot by itself supply capacity, but it can stimulate and fashion talent and above all, it can redeem from the danger of constricted views Thus the university becomes a potent instrument for good to a community, the strength of which is measured by the capacity of the individuals who compose it The university is the handmaid of the State of which it is the microcosm—a community in which also there are rulers and ruled, and in which the corporate life is a moulding influence

Speaking of the true and two fold function of the university Mr Haldane said it is a place of research where the new and necessary knowledge is to be developed It is the place of training where the exponents of that knowledge—the men who are to seek authority based on it—are to be nurtured and receive their spiritual baptism Such a university cannot live or thrive under the domination either of the Government or the Church Freedom and development are the breath of its nostrils, and it can or recognise no authority except that which rests on the be ... of the Truth to command obedience It was Lessing effect o... lared that were God to offer him the Truth in one mathema... the Search for Truth in the other, he would ledge ... Search and it is in the devotion to this search European re... high—a search which may assume an infinity of varied forms—that the dedicated life consists, the life dedicated to the noblest of quests, and not to be judged by apparent failure to reach some fixed and rigid goal, but rather by the quality of its striving.

Mr Asquith, Chancellor of the Exchequer, delivered his address as Rector of Glasgow University on January 11. He took as his subject "Ancient Universities and the Modern World" He said the mediæval universities had two characteristics, they were always in theory and almost always in practice cosmopolitan, and the true university has always been, in addition, catholic in its range A university never was, is not, and never ought to become a technological institute for the creation and equipment of specialists The limits of the knowable, wherever they are to be placed, have in these days expanded so far that no ambition and no assiduity is equal to the task of taking all that lies within them for its province Nothing can be more alien, then, from the business of a university than to produce the shallow and fluent omniscience which has scratched the surface of many subjects and got to the heart of none The fidelity of a university to the intellectual side of its mission must now, as always, be judged by the degree in which it has succeeded in enlarging and humanising the mental outlook of its students and developing the love of knowledge for its own sake Such an ideal does not imply a divorce of knowledge from practice When James Watt in 1756 came back to Glasgow from London the Corporation of Hammermen refused him permission to set up his business in the burgh because he was neither son of a burgess nor an apprentice The Faculty of Professors of whom Adam Smith was one, at once appointed him mathematical instrument maker to the University and gave him a room in the college buildings for his workshop It is often out of the mouths of professors and at the hands of universities that the practical man learns for the first time the real meaning and the latent possibilities of his own business In the long run a university will be judged, not merely or mainly by its success in equipping its pupils to outstrip their competitors in the crafts and professions It will be judged also by the influence which it is exerting upon the imagination and the character, by the ideals which it has implanted and nourished, by the new resources of faith, tenacity aspiration with which it has recruited and reinforced the untrained and undeveloped nature, by the degree in which it has helped to raise to enlarge to enrich, to complete the true life of the man and by and through him the corporate life of the community

Universities and the Schools

Presiding at a meeting of the Scottish Education Reform Association, held in Glasgow University on January 12, Mr Haldane spoke of the necessity for reform in Scottish university arrangements If teachers are to be trained there must be considerable elasticity, access to the university must be easy and yet difficult A man should not go there who is not fit to take a university training, and if he is not fit to take that he is not fit to be a Scottish teacher On the other hand, access to the university should not be a straight and narrow gate, accessible only to people who approach by one particular path If a high standard is to be secured in fashioning that elasticity, greater individual freedom must be given to each of the Scottish universities The Act of 1889 was passed in the days when what was called the federal idea was dominant If the Scottish universities were freed so that they might pass ordinances which would open their territories still wider and give a larger range in subject and vision, a greater elasticity in fashioning their degrees, it is certain that there would be no lowering of the standard, there would be a heightening In education, primary, secondary, and higher schools cannot be separated one from the other, they must be treated as one, and the teachers matter more to the schools than anything else Mr Haldane protested against the superstition that it is possible to form a judgment upon things that require a great deal of knowledge without possessing that knowledge The leadership in education in Scotland must be in competent hands, and the key to the situation is the raising of the *status* of the teachers in Scotland, and that is to be done by binding them more and more closely with the universities.

CORNELIUS O'SULLIVAN, F.R.S.

THE death of Mr. Cornelius O'Sullivan, F.R.S., which took place on January 8, at the age of sixty-five, has removed from amongst us a worker of great originality who, during the past thirty-five years, made his mark in various branches of pure and applied chemistry connected more or less directly with the industrial processes of brewing.

A native of Bandon, co. Cork, O'Sullivan developed a taste for science at a very early age, and having obtained a scholarship at the Royal School of Mines went through the three years' course with distinction, and became attached to the teaching staff of the Royal College of Chemistry, then in its old quarters in Oxford Street. In 1866 he became private assistant to Prof. A. W. von Hofmann, whom he accompanied to Berlin in that year. In the following year he entered the business of Messrs. Bass and Co. at Burton-on-Trent, where he ultimately became the head of the brewing and scientific staff, a post which he occupied up to the time of his death.

When O'Sullivan entered the brewing business the new ideas and discoveries of Pasteur with regard to fermentation were beginning to exercise a marked influence on brewing practice, and there seemed some danger of the new science of bacteriology occupying the field to the exclusion of chemistry. It is the special merit of O'Sullivan that, although very receptive of these new ideas, he clearly recognised that all the biological problems with which the brewer has to deal must ultimately be referred to the chemist, and he therefore set to work, in the first instance to investigate the nature of starch and the mode in which it is transformed under the hydrolytic agencies of diastase and acids. In these researches O'Sullivan made use of the polarimeter, and by a combination of the optical method with that of cupric reduction he elaborated processes for a study of the gradual disintegration of the starch molecule which have been employed by all subsequent workers. In following the course of the action of diastase on starch, he conclusively proved that the sugar which is formed is not, as was then generally believed, glucose, but a well-defined crystallisable biose, maltose, and that the dextrins which are simultaneously formed consist of several bodies differing amongst themselves by certain well-marked properties. His researches on the influence of temperature on the reaction led to certain valuable practical applications, with which every student of brewing technology is now familiar. The results of O'Sullivan's work on starch were published in the Journal of the Chemical Society between 1872 and 1879, and constitute a series of memoirs which are justly regarded as classical.

O'Sullivan then turned his attention to the amylans and other carbohydrates of the cereals, and also extended his researches to the gums of the arabin series and to gum tragacanth. Throughout the middle and later period of his life he studied the action of the enzyme invertase on cane-sugar, and in a remarkable memoir published on this subject, in collaboration with Tompson, there is a vast amount of information which seems destined some day to assist in finding a rational explanation of the mechanics of enzyme action.

In 1884 the Chemical Society marked its appreciation of O'Sullivan's work by awarding him the Longstaff medal, and in the following year he was elected a Fellow of the Royal Society.

The varied life-work of O'Sullivan affords an excellent example of the brilliant results which can be attained by the close union of pure science and technology, and of the constant reaction of one on the other. Of all our industries there is not one, with the possible exception of agriculture, which is able to suggest so many problems in chemistry, physics and biology as the ancient industry of brewing, and no one understood this better than the subject of this brief notice. Of his fine personal qualities and of the influence he had on the younger workers in a field which he made specially his own this is not the place to speak; suffice it to say that his generous, warm-hearted Celtic nature endeared him to a large circle of friends who are now mourning his loss.

NOTES

THE council of the Royal Astronomical Society has awarded the gold medal of the society to Prof. E. W. Brown, F.R.S., professor of applied mathematics at Haverford College, Pennsylvania, U.S.A., for his researches in the lunar theory.

THE Göttingen Königliche Gesellschaft der Wissenschaften has elected the following foreign members:—Prof. H. A. Lorentz, Leyden; Prof. L. Luciani, Rome; Lord Rayleigh, Pres.R.S.; and Prof. C. S. Sherrington, F.R.S.

THE council of the Royal Geographical Society has elected Mr. Roosevelt, President of the United States, an honorary member of the society. President Roosevelt has intimated his acceptance of this distinction.

PROF. E. L. NICHOLS, professor of physics in Cornell University, has been elected president of the American Association for the Advancement of Science for the meeting to be held next year at Chicago.

M. BOUQUET, director of technical instruction to the French Minister of Commerce, has been elected director of the Conservatoire national des Arts et Métiers for a period of eight years from January 1 last, in succession to M. Chandèze, who has retired.

WE learn from the *British Medical Journal* that the French Government has asked the Pasteur Institute to undertake an inquiry as to the distribution of malaria in various centres of colonisation in Tunis, especially the Béja, Mateur, and Goubellat regions, and as to the means of checking the prevalence of the disease.

THE Geological Society of London will this year award its medals and funds as follows:—Wollaston medal to Prof. W. J. Sollas, F.R.S.; Murchison medal to Mr. Alfred Harker, F.R.S.; Lyell medal to Dr. J. F. Whiteaves, of Ottawa; Wollaston fund to Dr. Arthur Vaughan; Murchison fund to Dr. Felix Oswald; Lyell fund to Mr. T. C. Cantrill and Mr. Thomas Sheppard; the Bigsby medal to Mr. A. W. Rogers, of the South African Museum, Cape Town.

NEW YORK UNIVERSITY has received a gift of about fifteen acres of land adjoining the south line of its grounds. The value of the property is, *Science* states, said to be between 40,000*l.* and 60,000*l.* From the same source we learn that Mr. Andrew Carnegie has given to the College of Physicians of Philadelphia 20,000*l.* toward the erection of its new building, on condition that a like sum be subscribed, of which 16,000*l.* has already been received.

WE announce with regret the death of the Very Rev. Robert H. Story, principal of Glasgow University, on January 13. For twenty-seven years Dr. Story was minister of the parish of Roseneath, and in 1886 he was appointed to the professorship of ecclesiastical history in the University of Glasgow. In 1898 he succeeded the Rev. Dr.

Caird as principal of the University He was mainly instrumental in raising a special fund of nearly 100,000*l* for improving Glasgow University

A REUTER message from Samarkand reports that the eclipse of the sun on January 14 was observed from a point at the 1481 verst on the railway between the stations of Kuropatkino and Mijulnskaja The first sign of the eclipse was noticed shortly after 9 a m, and at 9 53 the period of total eclipse set in, lasting for two minutes Throughout the time of observation snow was falling

IN celebration of the twenty-first year of work, the president and council of the Biological Society of Liverpool have invited members of the society and their friends, along with some distinguished biologists from other towns, to a conversazione to be held on Friday, January 25 in the museum and laboratories of zoology in the University of Liverpool The hon sec of the society is Mr J A Clubb, Free Public Museums, Liverpool

THE *Daily Chronicle* announces that a "zoo" for Yorkshire on an extensive scale has been definitely settled upon A twenty-seven acres site near Roundhay Park, Leeds, has been selected Herr Hagenbach, of Germany, is acting for the promoters of the scheme An ostrich farm is to form a leading feature A correspondent at Leeds informs us that the City Council, to whom Roundhay Park belongs, is not concerned with this project, which is a private venture for purposes of profit

A SET of Watson magnetographs has been installed in the new magnetic house at Helwan Observatory, near Cairo Egypt The equipment comprises recorders for declination, horizontal intensity, and vertical intensity The temperature coefficients of the intensity instruments are now being determined, and it is hoped that this work will be completed in February, and regular observations commenced

THE rules of the aeroplane race, which is to take place on July 14, 1908, are published in the Paris *Matin* of January 14 All the machines which start, without distinction of name or of form, but of French make, will be admitted as competitors Whatever may be the meteorological conditions on the date arranged, they will have to travel from the offices of the *Matin* in Paris to the office of the same journal in London within a maximum period of twenty-four hours, using only their own means of propulsion The winner of the race will receive a prize of 250 000 francs (10,000*l*.)

EARTHQUAKE shocks were felt in the following places on January 10 —*Christiania* —Two rather severe shocks of earthquake were felt at 1 30 a m they were accompanied by rumbling sounds The shocks were felt in towns on both sides of the Christiania Fjord *Frederikstad* —A slight shock was felt at 12 15 a m, a more severe one at 1 30 a m *Gothenburg* —Two severe shocks were felt in the district between Kornsjo and Mellerud at 1 30 a m A strong shock was also felt at Strömstad at the same time *Arvika* (*Wermland*) —A violent shock occurred at 2 25 a m *Upsala* —At 1 33 a m the Upsala seismograph recorded a slight shock which lasted twenty seconds A despatch from Honolulu on January 10 states that the Mauna Loa volcano, Hawaii, is in active eruption

A REUTER message from Kingston, Jamaica, announces that on January 14 the sixth agricultural conference, under the auspices of the Imperial Department of Agriculture, was opened there by Sir J. A Swettenham, the Governor Sir Daniel Morris delivered the presidential address, which reviewed the work accomplished by the department in developing tropical industries The attendance at the opening meeting was large, those present including men of science and agriculturists from all parts of the West Indies

A VIOLENT earthquake occurred at Kingston, Jamaica, at 3 30 on Monday afternoon, January 14, and caused great loss of life and property No details of the disaster are known at the time of going to press, but it is reported that many houses and other buildings have been destroyed by the earthquake and the fires which started immediately after the shock A Reuter message from New York states that cable communication with the Bermudas was broken on Monday night The Commercial Cable Company's lines to the West Indies are also interrupted The Hamburg-American Line Agency has received a message from Holland Bay, January 15 (5 38 p m), stating that a slight earthquake occurred there on Monday, but no damage was done The seismograph at the offices of the U.S Weather Bureau, Washington, recorded vibrations beginning at 3h 38m 23s, on Monday afternoon Mr Metcalf, Secretary for the U S Navy, has cabled to Rear-Admiral Evans, commanding the U S Fleet off Guantanamo, Cuba, directing him to investigate the extent of the Jamaica disaster and report to the Navy Department A *Daily Mail* correspondent at Christiania reports that an earthquake was felt on Monday afternoon at Trondhjem and over the greater part of northern Norway At some places the shock was severe enough to shake the houses

MR HALDANE, Secretary of State for War, has approved of the amalgamation of the Army Medical Advisory Board and the Army Hospital and Sanitary Committee The reconstituted Army Medical Service Advisory Board is composed of the following members —chairman, the Director-General, Army Medical Service, vice-chairman, the deputy Director-General, Army Medical Service Members Lieut -Colonel D Bruce, C B, F R S (as expert in tropical diseases), Colonel G K Scott Moncrieff, C I E, Assistant Director of Fortifications and Works, Lieut-Colonel C H Melville (as expert in sanitation) Civilian members Sir F Treves Bart, G C V O, C B, Dr J Rose Bradford, F R S, professor of medicine, University College London, Dr Louis Parkes, consulting sanitary adviser to H M Office of Works, Dr M S Pembrey, lecturer in physiology, Guy's Hospital, Sir Charles A Cameron, C B, professor of chemistry and hygiene, Royal College of Surgeons, Ireland Representative of the India Office Surgeon-General A M Branfoot, C I E Secretary Lieut -Colonel C H Melville

THE British Academy has received the sum of 10,000*l* for the purpose of establishing a memorial to the late Mr Leopold Schweich, of Paris. In accordance with the wishes of the donor, the endowment is to be called "The Leopold Schweich Fund," and is to be devoted to the furtherance of research in the archæology, art, history, languages, and literature of ancient civilisation, with reference to Biblical study There are to be annually not fewer than three public lectures—"The Leopold Schweich Lectures"—to be delivered in London, and as the ordinary rule in the English language, dealing with some subject or subjects coming within the scope of these studies The residue of the income of the fund, with all sums which may hereafter be added thereto by gift, bequest, or otherwise, is to be applied for the purposes of excavation, and for the publication of the results of original research in connection with one or more of the subjects named

It is with regret that we have seen the announcement of the death of Mr T R. Dallmeyer, who was for many years the managing director of the celebrated firm of J. H. Dallmeyer. He was the son of Mr J H. Dallmeyer, and grandson of Andrew Ross, and to a worthy degree carried on the work of these pioneer opticians Mr Dallmeyer designed several lenses and other photographic apparatus, but is best known as the inventor of the telephotographic lens Although it was found not to be an absolute novelty, its introduction as a practical photographic instrument was due to him He also worked out a modified combination for small cameras, the "Adon," which about doubles the linear measurement of the image without any loss of rapidity or need for focussing In passing away at so early an age as forty-seven, the optical and photographic world loses one from whom they seemed to have good reason to hope for much further service

The metric system is to be adopted at the works of Kynoch (Ltd) Mr Arthur Chamberlain, chairman of the company, has made a statement explaining that it is intended to carry out the whole of the clerical work, relating to interior economy, in metric units The clerical work relating to customers will only be shown in metric units so far as these measures are already in use with their customers carrying on business in countries that have already adopted the metric system We learn from the *Times* that Mr Chamberlain says the change will neither be expensive nor difficult Weights expressed in British units will be translated into kilograms, and the cost into decimals of a pound sterling This will be done by simple reference to a card of equivalents Thereafter in all its processes through the works an article will remain as so many kilograms at a decimal of a pound sterling per kilo In this way the cost of every article will be traced through all its processes in metric units and decimals of an English pound, but the selling price so arrived at will be changed into English currency The total cost of the introduction of the new methods of calculation is estimated at ½ per cent of a year's profits The saving on the other hand on clerical labour will repay this in the first year It will be seen that, so far from asking the clerks to learn anything fresh they will only be invited to forget old troubles

Cardiff has given a lead to the rest of Wales by the establishment of a public observatory Eleven years ago a suggestion was made in a local journal that a public telescope would be a most desirable acquisition Following on this, Mr Franklen Evans, J P, a well-known local man of science, offered to the town his 12-inch reflector and sidereal clock, the offer being made through Mr Arthur Mee, the then president of the Astronomical Society of Wales Various difficulties stood in the way and it was not until a couple of years ago that one of the councillors—Mr J A Kidd—took the matter seriously in hand, and succeeded in rousing his colleagues to carry it through In the meantime, the donor of the instrument had passed away When, however, the council really moved, it made up for previous indifference The telescope was put in thorough repair, and a suitable house built for it on Penylan Hill, which lies to the north-east of Cardiff, and is 250 feet above sea-level In the final arrangements invaluable assistance was rendered by Mr Albert Taylor, H M I S, who resides at Cardiff, and has had great practical experience in the construction and use of telescopes. The observatory, which was formally opened by the Lord Mayor, is controlled by a committee of which Mr Kidd is chairman, and consisting of city councillors and members of the Astronomical Society of Wales The telescope is clock-driven, and an attendant has been instructed in its manipulation and use An illustrated descriptive pamphlet has been prepared by Mr Mee and large numbers of people are visiting the observatory and viewing the heavens through the telescope

Staphilinid beetles, chiefly American, form the subject of part vi of vol xvi of the Transactions of the St Louis Academy of Science The author Mr T L Casey, takes occasion to mention that throughout the work he employs the term "America" as equivalent to the United States

Longicorn beetles from Selangor and Perak, described by Mr C J Gahan, of the British Museum, and a continuation of Mr H C Robinson's synopsis of the birds of the Malay Peninsula, constitute the zoological contents of No 4 of the first volume of the Journal of the Federated Malay States Museums

In the Proceedings of the U S National Museum (No 1428, vol xxxi pp 575–612) Mr W M Lyon describes a collection of mammals from the small islands of Banka, Mendanao, and Billiton, lying between Sumatra and Borneo Although many are described as new, nearly all are closely allied to well known species and none is of special interest

Parts ii and iii of vol xxxvi of Gegenbaur's *Morphologisches Jahrbuch* are entirely devoted to the comparative anatomy of the Primates, Mr G Ruge dealing with the characteristics of the liver throughout the order while Dr H. Bluntschli discusses the femoral artery in the lower catarrhine monkeys Both papers are of a highly technical character and of interest chiefly to specialists

We have received a copy of an illustrated "Handbook to the Perthshire Natural History Museum and Brief Guide to the Animals Plants, and Rocks of the County" The Perthshire Museum, as is well known, sets an admirable example to other institutions of the same nature in devoting its attention to the local natural history and in issuing this "Guide" (at the price of 3*d*) it will afford valuable assistance to local observers and collectors

In the December (1906) issue of the *American Naturalist* Prof H F Osborn completes his elaborate survey of the causes which have been most conducive to the extinction of the larger mammals As the result of this survey it is concluded that such extinction cannot be attributed to any one general cause Indeed, the chief induction which can be drawn from the investigation is that when the numbers of a species have been seriously reduced from some chief or original cause, various other destructive causes come into action, thus producing a cumulative effect which may lead to complete extinction In fact, from weakening its hold upon life at one point an animal species becomes subject to attack at many other points

To the January number of the *Naturalist* the Rev O P Cambridge communicates a note on the power possessed by certain spiders of the family Salticidæ of changing the colour of the large pair of eyes on the forehead Some time ago Mr. W W Strickland, of Singapore, announced the occurrence of this phenomenon in two species of Attis spiders from Java, stating that he believed such a change to be unknown in any other creature Mr Cambridge points out that Mr Strickland's observations were long ago anticipated, in the case of other species by the late Mr J Blackwall The same issue contains a

photograph of a basking-shark (*Selacho maxima*), measuring just short of 24 feet in length, taken in salmon-nets at Redcar in August last

IN the *National Geographic Magazine* for December, 1906, Miss E R Scidmore graphically describes Kedda-operations in Siam, accompanying her notes with reproductions of a number of photographs of a herd of elephants being driven towards the enclosure, and of the same herd, or individual members thereof, in the coral The Siamese Royal elephant hunt, which used to be an annual institution, is stated by the writer to be the largest affair of its kind in the world, but the steady increase of cultivation and civilisation in the country threatens the survival of the wild elephant The hunt represented in the photographs was held after the King's return from Oxford and America, and resulted in the capture of 250 elephants In Siam the tame elephant has apparently a much better time than its wild relative, the former looking sleek and well groomed, while the latter is gaunt and weather-worn with projecting ribs and patches of fungoid growth on its hide

WE have received the report of the Government bacteriologist of Natal, Mr H Watkins-Pitchford, for the year 1904-5 The greater part is occupied with experiments on, and results obtained by, the Rideal-Walker method of testing disinfectants Experiments were also made on the use of sulphate of copper for purifying water, a strength of one part of the salt to 75 000 parts of water being recommended as being both valuable and safe A nodular disease of the intestines of sheep, due to a small worm, is also described

THE Bulletin of the Johns Hopkins Hospital for December, 1906 (xvii, No 189), contains a second series of interesting reports on the comparative surgery of the lower animals, together with observations on distemper in dogs, from the latter it is concluded that the ætiological agent of this disease has not yet been definitely established Dr Knopf contributes an article on "Tuberculosis a Social Disease," which contains many useful maxims for the suppression of the disease

AS the result of an examination of material assigned to *Rhus glabra* from many different parts of the United States, Mr E L Greene, in a paper published in the Proceedings of the Washington Academy of Sciences, vol viii, separates from the species twenty-eight segregates of which five had previously been suggested as independent species While there is good reason for splitting the species the present affords a good instance in which the true value of the species would be best determined by cultivation and not merely as appears to have been the case from a study of herbarium specimens

WHEN engaged upon the inquiry into the devastations caused by bark-boring beetles among the "chilgoza" trees, Mr E P Stebbing was able to acquire an amount of information about the forests of Zhob, Beluchistan, and the Takht-i-Suliman Range in the North-West Frontier Province of India, that is embodied in the Indian Forest Bulletin No 7 The chilgoza, *Pinus Gerardiana*, highly valued for its edible seeds forms in parts extensive forests of fine trees 70 feet to 85 feet high and 9 feet to 12 feet girth, in a few localities the blue pine, *Pinus excelsa*, is associated with it in appreciable quantity Owing to indiscriminate collection of the cones, unrestricted grazing, and attacks of the boring beetles, it is shown that the forests, valuable alike for timber and their influence upon the water supply, require immediate conservation

OF the scientific papers published in the report for 1906 of the Missouri Botanical Gardens, the most important contributed by Mr. G. G Hedgcock deals with chromogenic fungi producing colour on wood A large number of fungi were carefully cultivated through various stages, and it was found that the blue, grey or brown, and black colours produced respectively by the genera Cerastomella, Graphium, and Hormodendron were contained in the fungus filaments, and no stain was exuded, but in the case of Penicillium and Fusarium the pigments were exuded and taken up by the wood cells A brief note by the same writer on zonation in fungus cultures, caused by alternations of day and night, relates to the results obtained under different monochromatic solutions On the subject of abnormal plant developments, Mr J. A Harris describes saccate structures, "ascidia," formed by the fusion of two leaves, or the edges of one leaf in Gasteria and Agave, and prolifications of capsicum and passion-flower fruits, while Mr H Hus refers to fasciation in *Oxalis crenata*

THE discovery of petroleum in the Gulf Coastal Plain of Texas and Louisiana has created a demand for specific knowledge of the geological relations of the oil The demand was for the time met by the publication in 1903 of a United States Geological Survey report The rapid development of the industry has necessitated a new examination of the fields, the results of which are given in a masterly memoir (Bulletin No 282) by Mr. N M Fenneman Detailed descriptions are given of topography, geology, and production of the Spindletop, Sour Lake, Batson, Saratoga, Matagorda, and minor oilfields and useful information on the utilisation of the petroleum and on the methods and cost of well drilling is appended

THE Geological Survey has prepared a very valuable memoir on the oil shales of the Lothians (Ordnance Survey Office, Southampton, price 4s) The memoir covers 194 pages, with three plates and sixty-four illustrations in the text, and is divided into three parts The first by Mr H M Cadell and Mr J S Grant Wilson, treats of the geology of the oil-shale fields The second part, by Mr W Caldwell, an experienced mining engineer, gives an account of the methods of working the oil shales The third part, by Mr D R Stewart, chemist to the Broxburn Oil Company, deals with the chemistry of the oil shales and the processes and products of manufacture The whole report, which has been edited by Dr Horne, forms the most complete monograph that has been written on the important oil-shale industry of Scotland The first published description of the oil shales was a short paper contributed by Mr Cadell to the British Association in 1885 More detailed accounts were contributed by him to the Iron and Steel Institute in 1888, and to the Institution of Mining Engineers in 1901 In the course of the recent revision of the Carboniferous areas of the Lothians by the Geological Survey, Mr Wilson obtained much further information Among the more important results are the determination of the outcrops and lines of fault owing to the recent mining developments in the Tarbrax, Cobbinshaw, Pumpherston and Breich fields, and the mapping of the new shale field at Ingliston The recent discovery of valuable oil shale near Duddingston may have a vital bearing on the future development of the industry The importance of the industry in Scotland is shown by the fact that in 1904 a total of 2,332,000 tons of oil shale was mined, yielding 62,932,000 gallons of crude oil, from which was produced 2,517,000 gallons of naphtha, 17,000,000 gallons of illuminating oil, 38,000 tons of gas oil, 39,500 tons of lubricating oil, 22,500

tons of wax, and 49,600 tons of sulphate of ammonia The coloured geological map and the sections accompanying the memoir are excellent, but the illustrations in the text are crude and roughly reproduced

In the *Electrician* of January 11 is an interesting article by Mr. G W Pickard on the measurement of received energy at wireless stations, reprinted from the *Electrical Review* of New York which should appeal to all who are watching the development of wireless telegraphy The method described by the author is both simple and useful, and does not require an elaborate arrangement of instruments A telephonic mode of reception is employed, and the sound of a single spark at the sending station is reproduced in the telephone by the discharge of a local condenser through the same receiving circuits, the charging potential of the condenser being made equal in intensity by variation until this is accomplished The periodicity of the condenser discharge is the same as that of the received energy Then knowing the potential and capacity of the condenser, the energy can be deduced by a simple formula An objection to the method is the difficulty in comparing successive sounds, which cannot be accomplished with any degree of accuracy Also a slight change of spark-length at the sending station would seriously affect results, and therefore make comparisons of the sending station's performance from day to day almost impossible The author mentions a method by which this may be partly overcome by the insertion of a key in the detector circuit, so as to secure the sending of a truly single spark At the same time, the method described will be useful as a rough test in practical work, and should help towards the solution of a true formula for long-distance work

We have received from Mr I A Vaughton, Sutton Coldfield, a communication entitled "'Growing' Alumina," which gives particulars of phenomena observed during the passage of electric sparks between a globule of mercury, acting as anode, contained in a drawn-out capillary tube placed vertically a few millimetres above an aluminium plate, which serves as kathode While sparks are passing, a circular "crater" composed of nearly pure alumina in a light, feathery form grows round the sparking spot, and after a short time the quantity of the product formed is considerable In appearance it resembles moss, when examined with a lens during its formation, filaments are seen to shoot along the surface of the aluminium in definite directions If the sparking be stopped and the deposit removed, the formation of the moss again occurs without the current being necessary, and the process may be repeated several times in succession In an atmosphere of hydrogen no alumina is formed, and in oxygen but little growth occurs The alumina produced acts on a photographic plate even through celluloid A contributor to whom we have submitted the communication informs us that the phenomena are probably due to the formation of aluminium amalgam owing to mercury being sprayed upon the plate by the sparks It is decomposed by atmospheric moisture, giving alumina and mercury, which is free to repeat the process Little action occurs in oxygen because of the need of a supply of water vapour The photographic action occurs owing to the production of hydrogen peroxide, which will attack a photographic plate through celluloid, hydrogen peroxide is generally formed in similar oxidations

The Memoirs of the Liverpool School of Tropical Medicine, twenty-one of which have been published, are to be superseded by a periodical which is to be issued by the school under the title of *Annals of Tropical Medicine and Hygiene* The annals will be edited by Prof Ross, in collaboration with Drs Stephens, Todd, Thomas and Breinl, Mr Newstead, and Sir Rubert Boyce

The report on the scientific results of the voyage of the S Y *Scotia* is to be published in six quarto volumes by the Scottish Oceanographical Laboratory The first volume will contain a narrative of the voyage and a summary of results, the second will deal with the physical results of the expedition, the third with botany, geology, and cartography, and vols iv v, and vi with the numerous branches of zoology The work will be fully illustrated with maps, plates, and photographs Each volume will consist of several parts, which will be published separately when ready Vol ii will be issued first, and will be ready immediately It will consist of five parts, dealing respectively with meteorology, magnetism bathymetry, physics of the ocean and tides and waves Orders, accompanied by a remittance for vol ii, 42s should be sent to the director Scottish Oceanographical Laboratory, Surgeons' Hall, Edinburgh

OUR ASTRONOMICAL COLUMN

The Temperature of the Moon —In a paper appearing in the *Astrophysical Journal* (No 5, vol xxiv), Mr F W Very discusses Mr Coblentz's recently-published conclusion that, from an investigation dealing with the reflection of heat radiations from various mineral substances, it may be deduced that the apparent temperature of the lunar surface is chiefly due to reflected solar radiations, and that the *actual* temperature may be about −225° C, in accordance with Langley's first conclusion Mr Very points out that his investigations of the radiations show that the larger part of them are not merely specularly reflected, but are radiated, the moon having first absorbed the heat from the solar radiations Instead of −225° C he suggests that the temperature of the lunar body may reach a maximum of about 100° C, the corrected lunar-radiation curve being similar to that appertaining to bodies not much below the temperature of boiling water

The Helium Line, D_3, in the Solar Spectrum —In a communication to the *Observatory* (No 379) Mr Buss of Ashton-on Mersey, states that he has repeatedly seen the helium line, D_3, as a dark line, when examining parts of the solar disc, within the sun spot zone, on which there were no telescopic signs of unusual activity He has previously recorded the appearance of this line in the region of various spots but never in the spot umbra itself and thinks that it might be found very often if continuous observations were made for the purpose He also suggests the possibility of D_3 being a regular feature of the Fraunhoferic spectrum the line being too fine to be seen with our present instruments except on occasions when the region examined is subject to some slight disturbance

A White Spot on Jupiter's Third Satellite —In No 4147 of the *Astronomische Nachrichten*, Senor José Comas Solá, director of the Fabra Observatory records the observation of a white spot near the north pole of Jupiter's third satellite on November 23, 1906 The observation was made with powers of 450 and 750 on an equatorial of 38 cm aperture, and with the latter magnification the spot was seen, with great facility as being intensely white and bordered by a very dark area Senor Solá thinks that much smaller instruments may reveal this feature With a steady image other, dark spots were seen, the whole disc of the satellite appearing as a reduced image of Mars The observation was made between 13h and 14h 15m, but no displacement of the spot was detected

A Remarkable Nebula —On some plates taken during September, 1906, Prof Max Wolf has found an extended nebula near to the star 20 Ceti Practically all extended nebulosities are situated in or near to the Milky Way, but this is a remarkable exception, for it is removed some

70° from the plane of the galaxy, the position of its densest part being $\mathrm{RA} = 0^{h}\ 57{\cdot}4^{m}$, dec $= +1^{\circ}\ 20'$ (1885).

This nebulosity is also remarkable in appearance; around the densest region there extends a quantity of nebulous matter of varying intensity showing small clouds of increased intensity at several points. Further out the intensity becomes so feeble that it is impossible to define its limits, and Prof. Wolf expects that a longer exposure than the four hours which he gave may materially extend the nebulosity seen on the plate. Three B.D. stars are involved in the cloud, which extends about 40′ in declination and 30′ in R.A. When examined under the microscope the brighter parts of the image are filled with numerous minute spots and short trails, and Prof. Wolf thinks it possible that the cloud may consist of a multitudinous congregation of very small planetary nebulæ, which a more powerful instrument may be able to resolve. The present plates were taken with the 16-inch Bruce telescope (*Monthly Notices*, November, 1906).

PERIODICAL COMET DUE TO RETURN IN 1907.—Only one periodical comet is due to return during the current year, that discovered by Giacobini at Nice on December 20, 1900. As observed then it was very faint, and showed only a small nebulous disc, without any tail. As its period is about seven years, according to the elements calculated by Prof. Kreutz, and as it passed through perihelion about December 3, 1900, it is not likely to be rediscovered until nearly the end of the present year (the *Observatory*, No. 379).

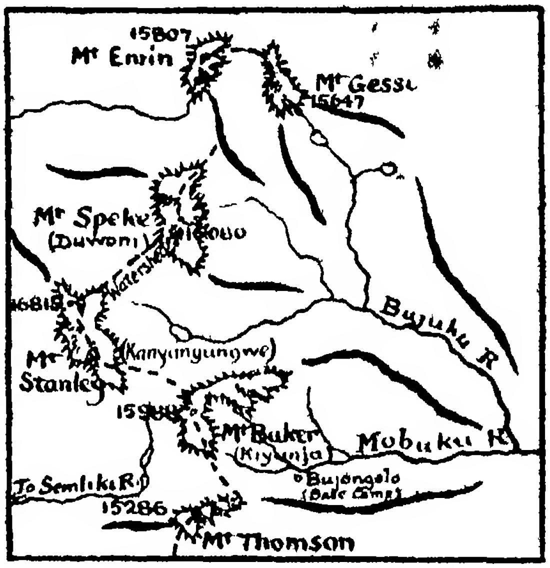
ORBITS OF THREE DOUBLE STARS.—The results of an investigation, by Prof. Doberck, of the orbits of ζ Cancri, ω Leonis, and H I 39 (Σ 3062), are published in Nos. 4144–5 of the *Astronomische Nachrichten*. The author gives a set of elements for the orbit of each system, and compares all the available observations with the calculated places; from a discussion of the whole he gives the probable error of the annual means of each observer's measures. According to the final elements, the respective periods of these three systems are approximately 60, 116.7, and 105.5 years.

THE DUKE OF THE ABRUZZI'S ASCENTS IN THE RUWENZORI RANGE.

AT a crowded meeting of the Royal Geographical Society, held at the Queen's Hall on January 12, and honoured by the presence of the King and the Prince of Wales, the Duke of the Abruzzi gave an interesting account of his recent exploration of the snowy summits of the Ruwenzori range. It will be remembered that many attempts on these peaks have been made within the past few years, but that, owing rather to the climatic character of the range and its distance from an accessible base than to special difficulties from a mountaineer's point of view, all the Duke's predecessors had failed to reach its culminating point. Profiting by the experience of these, the Duke was able to avoid the causes of their failure, his expedition being provided with all that forethought could suggest in the way of equipment, while he was also fortunate in securing trustworthy information as to the times of year at which the climatic conditions were likely to be most favourable.

The Duke was accompanied by two Alpine guides and two porters, all from Courmayeur, as well as by experts entrusted with research in various scientific departments, including Major Cagni, his trusty companion on his previous expeditions, and Signor Sella, well known for his unique experience in mountain photography. Apart from the mountaineering interest of the expedition, there was much to be done before the topography or morphology of the range could be at all thoroughly understood. Captain Behrens, of the Anglo-German Boundary Commission, had, by triangulation, fixed the altitude of the highest summit within very narrow limits, and shown that it was much under the 20,000 feet attributed to it by some travellers. He had also fixed with considerable accuracy the position of the double culminating peak, recognised as the Kanyangungwe of Stuhlmann, but the number and relative positions of the several *massifs* were still matters of uncertainty.

It is unnecessary to refer to the first part of the Duke's address, dealing with the journey from the coast and final organisation of the expedition. The route adopted (after much deliberation) for the approach to the snows was that from the east by the Mobuko valley, followed by Moore, Johnston, Grauer, and others. During the toilsome march up this the Duke saw reason to doubt its being the best, and he subsequently found that the Bujuko, a northern branch, or even the main head-stream, of the Mobuko, possessed some advantages. After the usual difficulties had been overcome, the snows were at last reached, and a view of all the peaks obtained from a ridge running east from Kiyanja. To the north, four distinct snowy mountains, separated by well-marked depressions, were in view, the nearest and most westerly being crowned by two pairs of peaks, the loftiest of which were at once recognised as those seen from Butiti both by Freshfield and the Duke, while evidently quite distinct from the Duwoni of Johnston. This had already been suspected by Mr. Freshfield after receiving the account of Mr. Wollaston's ascents. After ascending to the summit of Kiyanja it was decided to make a circuit to the south of this mountain, and after descending into a valley belonging to the



Rough Sketch of the Ruwenzori Peaks.

Semliki system, to strike north for the saddle between the two highest peaks. During the descent of this valley a striking sunset view over the great Congo forest was obtained, and the Duke's description was well reinforced by one of Signor Sella's striking photographs. The ascent was successfully accomplished by the Duke and the guides on June 18, the chief difficulty arising from the mists and from an overhanging cornice, which required great care to negotiate. A peculiar feature was the presence of huge "ice-stalactites," which supported the cornice. The twin peaks received the names of the Queens of Italy and England. Between June 22 and July 10 the Duke ascended all the main peaks, while his coadjutors prosecuted their own several tasks, Major Cagni completing an excellent map, while Signor Sella pursued his photographic labours, of the admirable results of which the audience had many specimens.

To the individual *massifs* and peaks the Duke has given the names of distinguished explorers of the region and of Royal personages, although it may be doubted by some whether the native names which have already found their way into Ruwenzori literature are not more in harmony with the romantic aloofness of the range than any exotic appellations, however otherwise suitable. Even though not strictly belonging to the summits, the native

names might as legitimately be transferred to the latter as many of the names in use in the Alps and elsewhere. An interesting point brought out is the fact that all the snowy massifs lie on the main water-parting of the range. As regards its geology, the theory of a volcanic origin may be absolutely excluded, there being only one spot in the whole upper region at which even local traces of basaltic veins were seen. The evolution of the range may be ascribed to (1) an upheaval *en masse* of a portion of the Archæan floor of Central Africa; (2) to a highly accentuated anticlinal uplift, ellipsoid in form, with strata more or less tilted in the central group; (3) the presence in this of a series of rocks (amphibolites, diorites, &c.) far more resistant than the gneisses and mica-schists of the outer ranges. Evident traces were seen of the enormous development of glaciers in the Ice age, while at present they are of the second order only, on the upper slopes and in the larger ravines. They are all at the present moment in retreat. The snow-line seems to be at about 14,400 feet. Among other results of the expedition, various new species of birds, molluscs, insects, crustacea, &c., were collected, though the *fauna* of the upper region was naturally poor.

The Duke showed a praiseworthy caution in identifying the range with the "Mountains of the Moon," in spite of the obvious allurements of the notion, to which so many of his predecessors have succumbed.

At the conclusion of the address the King, in a short speech, expressed the thanks of the assembly to the Duke, whom he congratulated upon his successful expeditions in tropical and polar regions.

METEOROLOGY IN PERU.[1]

IN 1892 Prof. W. H. Pickering and others of the staff of the Arequipa Observatory were trying to establish meteorological stations in Peru, a region which up to the present has not been very well represented in meteorological observations. The meteorological station at Mollendo had been discontinued during 1890 and 1891, but observations were resumed there and at Arequipa during the early part of 1892, and in March a station was established at La Joya, a town midway between these two places.

In December, 1891, Messrs. Douglas and Goodair made a journey of inspection past the Chachani Ravine, behind Arequipa, and ascended the main Chachani summit to an altitude of 18,000 feet, being satisfied that the ascent could be completed. In January, 1892, Prof. Pickering established a station at the Chachani Ravine at an altitude of 16,650 feet. An attempt was made in December to start a station on the main summit, but when Prof. Pickering and Mr. Goodair reached a height of 18,800 feet the Indians who were carrying the instruments and baggage deserted, and the attempt failed. The Chachani Ravine station was visited about once a month during 1892, and discontinued in 1893.

In October, 1893, a station was erected on the summit of the Misti Volcano, and in December another lower down on the eastern flank, the altitudes being 19,200 feet and 15,600 feet respectively. In 1895 observations were also taken at an altitude of 13,300 feet.

These stations constituted a chain from the sea coast over the western Cordilleras, and in order to continue this chain across the Andes, Prof. Solon I. Bailey, in July, 1894, started a station at Cuzco, in the valley between the western and eastern Cordilleras. The instruments were established in the yard of a brewery, and one of the employees commenced observations in July.

The Meteorological Station at the Chachani Ravine (16,650 feet).

After an unsuccessful attempt to secure a station to the east of Cuzco, Prof. Bailey went on northward, using mules and encountering many difficulties on the way. Very often the shelters and instruments had to be carried by hand under the low branches of trees and overhanging rocks which would otherwise have struck them from the backs of the mules. At Santa Ana Prof. Bailey met one of the estate owners, who willingly agreed to make the observations in his own grounds, and did so for more than a year.

The various stations were all fitted with Richard barographs and thermographs, standard and maximum and minimum thermometers, &c. Observations were also made of rainfall, clouds, winds, and of occasional phenomena.

At Mollendo, La Joya, and Cuzco observations were made at 8 a.m., 2 p.m., and 8 p.m. each day, but at Santa Ana only at 8.0 a.m. At the mountain stations observations were made only at intervals of about ten days by various members of the Arequipa staff.

In the volume under notice only eye observations have been discussed, the automatic records being left for a future volume. So also are all the Arequipa records.

An examination of the thermometer records shows that the annual range of mean temperature at the lower stations is small, being largest at Mollendo on the coast.

[1] "Annals of the Astronomical Observatory of Harvard College." Vol. xxxix., part ii., Peruvian Meteorology, 1892-5. By Prof. Solon I. Bailey.

where the range is from 59°·9 F, in August, to 71°·6 F, in February, only 11°·7 F, whilst at Cuzco the range is only 6°·1 F.

At Mollendo and La Joya, both west of the mountains, the south and east winds predominate very largely, whilst at Cuzco and Santa Ana there is no marked preponderance of wind from any particular quarter.

During the period April, 1892, to December, 1895, the total rainfall at Mollendo was 2·65 inches, the mean annual rainfall being 0·66 inch. At La Joya, which is in the middle of the desert of Islay, no measurable rain fell during the whole period, that is, never did more than one two-hundredth of an inch fall on any one day. On the average there are eight days per year on which some rain falls. The annual rainfall at Cuzco is 38·58 inches, and the rainfall for the year July, 1894, to June, 1895, at Santa Ana was 51·71 inches.

All the observations made by eye are given in full, and are well summarised. The dated remarks which accompany the tables prove very interesting reading, especially those referring to the high stations, and show well the difficulties encountered in making observations at these altitudes, exposed to wind and cold, and apparently also to robbers, for on September 6, 1894, it is recorded that at the Misti summit station the doors of the hut and shelter were found open, and that the barograph, thermometers, and tools had been stolen!

As an appendix an account is given of the moving sand dunes of the desert of Islay. Scattered over this desert are thousands of these crescent-shaped dunes. They are all of one form, and have always the same orientation, with the convex side to the south winds and the cusps pointing north and north-west.

Prof. Bailey measured one of these dunes near La Joya in 1894. The points were 160 feet apart, and the length round the convex side was 477 feet. Its maximum width was more than 100 feet, and the weight was estimated as more than 8000 tons.

Between March, 1892, and March, 1894, it had travelled 125 feet, and by March, 1896, a further 120 feet. From that date until January, 1901, monthly measures were taken, and in the five years it travelled 294 feet at an average rate of more than 5 feet per month. A comparison of the record of movement and the record of strong south winds shows that these winds are the sole cause of the northerly movement of these sand dunes. W. M.

THE ASSOCIATION OF ECONOMIC BIOLOGISTS.

ON Wednesday, January 9, the annual meeting of the Association of Economic Biologists opened at Cambridge, and continued until Friday, January 11. The conferences were held by kind permission of the medical staff in the pathological department of the University, and the laboratories in this department and also the zoological laboratory were thrown open for the occasion, and members also had the opportunity of visiting the botanical department.

Mr. A. E. Shipley, F.R.S., was elected president of the association for 1907 in the place of the retiring president, Mr. F. V. Theobald, who with Sir Patrick Manson, K.C.M.G., and Prof. W. Somerville, will act as vice-presidents for the year.

In his presidential address Mr. Shipley dealt with the subject of sea fisheries. He gave an interesting account of this important subject, and dwelt on the necessity of constant investigation. No less than 27,000 vessels are engaged in this industry, employing 90,000 men, fishing from British ports, the capital invested being estimated at 11,000,000*l*. He referred to the partial failure of the herring fishery last summer, and to the numerous inquiries that had been held concerning such matters, recounting no less than seventeen in the last seventy years.

The president is of opinion that time is not yet ripe for deep-sea fishing legislation, on account of our knowledge still being so deficient that it does not yet form a sound basis for law making. The North Sea fisheries are those upon which our energies must be mainly expended. Fishermen and experts have long held that the grounds are being depleted, and the latest report of the Board of Agriculture and Fisheries bears out these statements.

Mr. Shipley then mentioned various experiments that had been carried out in Norway and on the Dogger Bank. Some interesting figures regarding fish reproduction were quoted, showing their enormous sexual powers, for instance, the turbot produced annually 8½ million eggs and the cod 4½ million.

The chief possible causes of impoverishment were summed up as follows:—(1) the accumulated stocks of the Dogger and Iceland grounds had been fished out; (2) any given area of sea could support but a limited quantity of produce; and (3) the excessive destruction of young fish. In spite of the grave nature of the North Sea problem, it is satisfactory to learn that the condition of the fishing industry generally was never more prosperous than at the present time. It is hoped that sufficient funds will be forthcoming to continue the excellent scientific work in this subject that has already been done.

Prof. Nuttall's paper on red-water fever and allied diseases was full of interesting matter. After explaining the results of his investigations into the life-history of the Piroplasmæ he dealt with the various diseases caused by them, dwelling particularly on the results of his experiments on canine piroplasmosis. In connection with this paper Prof. Nuttall and Mr. Warburton had prepared a most interesting exhibition of ticks, and the parasites they convey.

The first day's proceedings finished with a paper by Mr. R. H. Biffen on his well-known work on cereal breeding.

The first paper on Thursday was one by Mr. F. V. Theobald on some new hemipterous fruit pests. Illustrated by lantern-slides, the life-history and damage caused by leaf-hoppers (Typhlocybidæ) were fully entered into. There had been no complaint of these insects by fruit-growers until last year, when some species occurred in such numbers that they even stopped picking. Besides mentioning results obtained in the treatment of these pests, Mr. Theobald discussed the parasites which affect the Typhlocybidæ, amongst the most interesting being some small Proctotrupids which cause "parasitic castration," one genus, Aphelopus, having occurred during the past year in such numbers that the opinion was expressed that the "hoppers" must have been nearly stamped out in places.

A long paper followed on the American gooseberry mildew, by Mr. Salmon, who explained its life-history and the great damage it does, and dwelt upon the necessity of immediate steps being taken to stamp it out and prevent importation. The paper caused some discussion, in which Profs. Middleton, Percival, and Fisher joined.

The secretary (Mr. Collinge) then gave a short and concise description of his successful extermination of the black-currant gall mite by means of sulphur and lime. Dr. MacDougall read a paper on parthenogenesis in the pine sawfly, and then gave an account of an extremely interesting piece of work on the length of life of *Calandra granaria*. At the afternoon sitting Mr. Freeman dealt with the geographical distribution of rubber plants, and incidentally stated that the output last year was 70,000 tons, valued at 30,000,000*l*. Of this, 63 per cent. came from tropical America and 34 per cent. from tropical Africa, the remainder from Asia, the output of cultivated rubber being only 1½ per cent. to 2 per cent. of the world's output.

Mr. E. R. Burdon then read a paper on the spruce-gall and larch-blight diseases caused by Chermes, and traced the connection between the two aphides and their migrations.

The day's proceedings terminated with a paper by Mr. F. V. Theobald on the insect pests of the British East Africa Protectorate, giving an account of the chief insect pests received from the Imperial Department of Agriculture. The most interesting is the diamond-back moth, which is thought to have been introduced into Africa, but which Mr. Theobald believes to be indigenous, in which Prof. Carpenter entirely agreed.

The final sitting was held on Friday morning, January 11, when papers were read by Mr T Strangeways, on a description of an infectious disease occurring in hares, by Mr E. G Fearnsides, on the blood changes in man caused by the presence of metazoan parasites, and their aid in diagnosis, and the use of an economic museum in the teaching of geography, by Mr W G Freeman Some valuable observations were brought out in Mr Fearnside's paper on the changes observed in the blood in parasitic attacks and the production of toxins by the parasites Mr Warburton exhibited an apparatus for extracting small mites, &c, from moss, invented by Prof Berlese, who contributed a paper on the olive-fruit fly and its treatment

The next annual meeting will take place at Edinburgh in Easter, 1908, a meeting was also arranged for July in London

Mr Walter Collinge, of Birmingham University, is still continuing the secretaryship

THE PUBLIC SCHOOL SCIENCE MASTERS' ASSOCIATION

THE annual meeting of the Public School Science Masters' Association was held on Saturday, January 12, at the University of London, the president, the Rev and Hon E Lyttelton, headmaster of Eton, being in the chair

The president, in his address on the place of science and of literature in a general education, prefaced his remarks with the opinion that a classical headmaster had one great advantage when criticising a science lesson in that his total ignorance of the subject placed him in the position of the most backward of pupils, and enabled him to ascertain exactly when the lesson was successful in producing the required impression on the mind of the learner In the discussion of educational matters there were the dangers of cloudiness from ignorance and of dogmatism which afforded no contribution to the discussion Science was calculated to diminish these two dangers By science he meant experimental study, and not the form of class demonstration sometimes, in the old days, combined with lax discipline, the object apparently being to provide a sort of agreeable change in the regular work of the schoolboy

As now understood, general education meant that given to boys up to the age of sixteen, and the arguments following were in favour of science being taken seriously before that age It would be conceded that science aroused more interest, at least in its initial stages, than was the case with any other subject, save religion, but it was a question whether this interest did not fall off later when more brain work was required This was so with classics The practical question, however, was not whether science interested the boy more than did the classics, but whether science and literature should go on together The boys who were apparent failures at classics might be found successful later in science Huxley had said that in science young minds were brought into contact with facts It was not so very different in the case of literature The advantages claimed for science in educational effects, training in inductive and deductive methods, and freedom from following mere authority, were shared by most other subjects when these were taught by modern methods These newer methods were certainly due to the influence of science teaching

The advantages of experimental science might be said to consist in the constant application to reason, truth, the senses of touch and sight, the virtue of patience and accuracy Science brought the pupil into association with the great army of discoverers, and illuminated daily life with its stimulating powers, leading to the exercise of the precious faculties of imagination and wonder The president pleaded for training leading to ambidexterity, and referred to the healthful mental effect afforded by exercise of both sides of the brain, pointing out that many school games were lacking in this respect The results of scientific and of literary teaching both depended upon the enthusiasm of the teacher, but this was especially true of the latter One advantage of literature was that it brought the learner more into contact with human affairs generally and although some of the faculties touched were the same as in the case of science, there were others not so influenced They were not called upon to decide between two subjects There was room for both, teachers of science and of classics should be co-workers Literary teachers should be able to save the science masters the labour of teaching the art of making notes in correct style The classical failures should be rescued by science The classical teacher called to the science teacher for help with new devices to touch the imagination and awaken hope—for something to haunt startle, or waylay the young minds, to make them feel the joy of learning

Sir Oliver Lodge said that to eliminate the heat retained rather than generated by cloudiness of thought and fog of dogmatism, it was necessary to admit the clear and bracing atmosphere of science He agreed that ambidexterity was to be encouraged There were three kinds of boys, the docile, the eager, and the unwilling, each of whom required different treatment But it was necessary to consider the average boy The quantitative side of science should not be overdone In that respect subjects differed, in the study of heat, quantitative work was desirable in the earliest stages, but in electricity he thought it better at first to allow an acquaintance with phenomena, proceeding later to measurement The teacher should excite interest rouse curiosity, feed only the hungry, and not stuff with information *apropos* of nothing Sir Oliver suggested that astronomy and physiology might be taken in schools, and that astronomy should be treated in a manner not too technical, but rather on biographical lines One should begin at both ends of a subject, but in different ways, for science was both inductive and deductive and this method of learning would use both qualities He advocated the pupil's going "behind the scenes", he should read examination answers, perhaps set examination papers In learning a language a boy was apt to consider he was dealing with chaos so many forms of words occurring *e g* changes in stem of verbs, for which he could see no reason Were the boy set to construct a language, he would see the necessity for and realise the meaning of tenses and cases Boys should be encouraged to read the classics of science and then they would get to appreciate the spirit of scientific investigation, which should be carried into all their studies Books should be used in order to learn how to acquire knowledge at first hand, problems should be thought out before information was gratuitously supplied A literary education was possibly best on the psychical side, but it did not give a knowledge of the material universe and no educated person should be deprived of this

Prof Tilden thought the system of classical and scientific sides in schools was insufficient There were, for instance, artistic minds which did not respond to either of these divisions The president, replying to Mr J Talbot (Harrow) said he agreed that science should have a liberal allowance of time in the curriculum something quite different from simply two hours per week, and in reply to the Rev A L Cortie, S J (Stonyhurst) he advocated commencing the subject at, say six or seven years of age Mr Thwaites (Wyggeston Schools Leicester) gave the results of some inquiries he had made of the chief public schools In general, about 60 per cent of the boys take science, and of these about 95 per cent are in the general courses The average number in classes was 21 5 for the general and 14 for special courses The former were allowed, on the average four hours per week for two subjects and the latter twelve hours In twenty three schools there was one science master for every twenty six boys He considered it was now time for the schools to agree upon the subject-matter of their science courses

Mr F R Leyland-Wilson (Charterhouse) read a paper on the best method of introducing the atomic theory in science

An exhibition of apparatus by members and manufacturers was held at the close of the meeting

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

MR EVAN SPICER, chairman of the London County Council, will distribute the prizes and certificates at the annual conversazione of the Northampton Institute, Clerkenwell, E C, on Friday, January 25

THE annual general meeting and dinner of the Central Technical College Old Students' Association will be held at the Trocadero Restaurant, Piccadilly Circus, W, on Saturday, February 23 Applications for tickets should be sent to Mr R J Caldwell, 40 Salehurst Road, Crofton Park, London S E

THE department of archæology of the University of Pennsylvania has received a gift of 8000*l* from Mr Eckley Brinton Coxe, jun The donor has specified that of the gift 1720*l* a year shall be paid for five years to the new curator of the department of Egyptology Dr D Randall MacIver, who is now in Egypt, where he has been instructed to begin excavations

MR SIDNEY WELLS, principal of the Battersea Polytechnic and a member of the consultative committee of the Board of Education has been appointed Director General of the Department of Agriculture and Technical Education for Egypt This department has been created in order to develop, organise, and control technical education in Egypt generally It will be concerned with all the Government educational institutions of every kind, and also with the non-Government technical institutions

A PRIVATE donation has enabled the Meteorological Committee to invite applications for an appointment as reader in dynamical meteorology The readership will be of the annual value of 350*l*, and will be tenable for three years at any British university that may be approved for the purpose and affords the required facilities The duty of the reader will be primarily to promote the science of meteorology by mathematical investigation, and he will be expected to give annually a short course of about twelve lectures Further details may be obtained from the Director of the Meteorological Office, 63 Victoria Street, London, S W

THE annual report of the council of University College, London, has just been issued The number of students in the college for the session 1905–6 was 1396, of these, 134 were post-graduate and research students The report contains particulars of the benefactions received during the year, which include valuable grants from the Drapers' Company from the Chadwick trustees, and the sum of 2500*l* collected by the Jewish Historical Society for the maintenance of the Mocatta library The report also contains a summary of the research work done during the past session, the lists of the publications by professors, assistant teachers, and senior students occupy fourteen pages The steps that have been taken for the union of the college and the University of London are summarised in the report On January 1 of the present year the college ceased to be a school of the University, and became incorporated with it, thus realising the aims of those who in 1826 founded it It is the first college to be thus incorporated with the University, and it is understood that its example will be followed by King's College Important additions have been made during the past year to the departments of physics and chemistry, and a plan has been worked out for the rearrangement of many of the college departments This will be possible when the new buildings for the school of advanced medical studies, now in course of erection by the generosity of Sir Donald Currie and the new buildings of University College School at Hampstead, are completed

SOCIETIES AND ACADEMIES.

LONDON

Mathematical Society, January 10.—Prof W Burnside, president, in the chair —An exhibition of models of four-dimensional figures was made by Mrs A **Stott.** The models are sections by three-dimensional flat spaces of the six regular hypersolids of a flat space of four dimensions The sections are in general polyhedra, and corresponding faces of different polyhedra, forming a series of sections of the same regular hypersolid, are coloured identically, in order to show the relations between the different sections. Other models show the grouping about a point of the regular hypersolids which have the space-filling property —The uniform convergence of Fourier's series Dr E W **Hobson** The coefficients of the Fourier's series determined by an assigned function are defined by integrals, which may be determinate when the extended definition of integration introduced by Lebesgue is used, although they have no meaning when integration is interpreted in accordance with Riemann's definition It is shown in the paper that whenever the coefficients of the Fourier's series, determined by a function $f(x)$ in the interval $\pi > x > -\pi$, are, in this sense, determinate, and the function $f(x)$ is continuous throughout a sub-interval included in this interval, and this function is of limited total fluctuation in the whole interval the Fourier's series so determined converges uniformly in the sub-interval —Hyper-even numbers and Fermat's numbers Lieut-Colonel A **Cunningham.** The hyper-even numbers are formed in sequence as 2^n 2^{2^n}, $2^{2^{2^n}}$, and so on. Fermat's numbers are of the form $2^{2^n}+1$ The numbers ξ which are such that $2^\xi \equiv 1 \pmod{m}$ are the *Haupt-exponents* of 2 for the modulus m The paper is occupied with tracing the relations which connect together the residues of successive hyper-even numbers, the uneven factors of the *Haupt-exponents*, and the Fermat's numbers —Riemann's hypergeometric function Dr E W **Barnes.** It is shown how the differential equation of the hypergeometric series, and likewise that of Riemann's function, can be solved respectively by means of certain contour integrals, and how the known solutions can all be obtained by deforming the contour The relations between the various forms of solution, which hold in the neighbourhoods of the singular points, can be traced very simply by means of the general formulæ The method is applied to obtain asymptotic approximations to zonal harmonics in the case where the index increases indefinitely —Partial differential equations of the second order, having integral systems free from partial quadratures Prof A R **Forsyth** The integral systems discussed are those in which three variables x, y, z are expressed in terms of two parameters u, v, an arbitrary function of u, an arbitrary function of v, and differential coefficients of these two functions The object of the paper is to determine the forms of the differential equations which possess integrals of the type in question and to construct the integrals of such equations —The singular points of certain classes of functions of several variables G H **Hardy** The theory of the singularities of functions of one variable, defined by Taylor's series, may be said to be tolerably complete, but in the case of functions of several variables little advance has been made The purpose of this paper is, by the consideration of a few of the simplest cases, to make a beginning with the problem of classifying types of power series in two or more variables according to the nature of their singularities —The singularities of functions defined by Taylor's series G H **Hardy**—Asymptotic approximation to integral functions of zero order J E **Littlewood** —The reducibility of covariants of binary quantics of infinite order P W **Wood.**—The forms of the stream lines due to the motion of an ellipsoid in infinite fluid, frictionless or viscous Dr T **Stuart.**

Geological Society, December 19, 1906 —Sir Archibald Geikie, Sec R S, president, in the chair.—The post-Cretaceous stratigraphy of southern Nigeria J **Parkinson.** In this paper, which is a first attempt to outline the sequence of the later deposits of southern Nigeria (now including the colony of Lagos), a series of beds is described from four localities—three from the western side of the Niger, and one around Calabar near the Kameruns frontier The alluvium of the river-beds and the lower terraces are referred to, and the succeeding sediments grouped under three heads —The geology of the Oban Hills (southern Nigeria) : J **Parkinson.** The country described in this paper comprises some 1800 square miles of the Eastern Province of southern Nigeria, adjacent to

the Kamerun frontier The rocks are crystalline, principally gneisses and schists, with later granites, pegmatites, and basaltic dykes, surrounded on the north, west, and south by Cretaceous sediments. For purposes of description the series is divided under nine headings, according to locality and petrographical character, and it is concluded that, neglecting the basaltic dykes, two broad groups may be distinguished—the one characterised by the presence, the other by the absence, of foliation In the former the foliation tends to be lost, giving a passage between types which petrographically are acid orthogneisses and granites.—The crystalline rocks of the Kukuruku Hills (Central Province of southern Nigeria) J **Parkinson** In this paper a short account is given of the crystalline rocks found in the Central Province of southern Nigeria, between the station of Ifon (north of Benin City) and the northern Nigerian frontier The rocks fall under two heads —(*a*) a group of gneisses, and (*b*) a group of schists

Royal Microscopical Society, December 19, 1906 —Dr D H Scott, F.R S, president, in the chair —Microscopic study of strain in metals F **Rogers**. The author described the nature of the fatigue of steels which is brought about by submitting them to alternating stresses of a certain magnitude The nature of the effects in the ferrite of steels is different from that in soft iron, and the effects in pearlite depend upon the type of pearlite An important difference exists between steels as rolled, or annealed below about 750° C, and steels annealed at higher temperatures, i e more or less overheated In the former, the outcrops of surfaces upon which slip has repeatedly occurred are very numerous, short and crooked, and the surface parallel to the direction of stress becomes ruffled In the latter type, the outcrops are fewer, less crooked, and longer, and the surface is practically unruffled A relation is found to exist between the ruffling and the Lüders's lines which are found upon statically-strained pieces, and this leads to the theory that specimens of the "normal" group endure fatigue better than "overheated" specimens, because the permanent and injurious microscopic strains are more minutely subdivided and uniformly distributed in the former than in the latter There is a stage in the life of a piece of steel enduring fatigue, after which, though it is far short of final rupture, annealing is futile, if not actually harmful Pieces in this stage if heated to 250° C or higher, and then fatigued to rupture, show heat-tint marks on the ultimate fracture, which map out the portion of fracture which was sufficiently open at the time of heating for air to enter

PARIS

Academy of Sciences, January 7 —M A Chauveau in the chair —The distillation of alloys of silver and copper silver and tin, and silver and lead Henri **Moissan** and Tosio **Watanabe**. Alloys of the above-named metals were heated under comparable conditions in the electric furnace, the current being maintained at 500 amperes at 110 volts The original alloy was analysed, and also the ingot remaining in the graphite crucible after the heating It was found that the metal most easily volatilised was lead, followed by silver, copper, and tin, tin having the highest boiling point of the four The results are in general agreement with the experiments of Krafft on the distillation of small quantities of metals in a kathode vacuum —The results of the micrometric measurements made during the eclipse of August 30, 1905 at Roquetas and at Saint Genis Laval Jean **Merlin** The value adopted by Newcomb for the constant of lunar parallax is not appreciably in error, and a better value cannot be deduced from the above observations A certain number of the relative positions of the sun and moon given in the *Connaissance des Temps* require correction —A theorem of Heine and a theorem of Borel A **Schoenflies**.—Turbines with a flexible axis L **Lecornu** In high-speed impact turbines of the Laval type there are certain advantages connected with the use of a flexible axis The present paper is concerned with the effects of this flexible axis upon the movements of the centre of gravity of the system, taking into account the small variations of the angular velocity of the turbine disc —The theory of the magnetic properties of iron beyond the temperature of transformation Pierre **Weiss**.—The measurement of the radio-chromometric degree by the electrostatic voltmeter in the utilisation of the Röntgen rays in medicine J **Bergonié**. The voltage of the Crookes's tubes being measured by an electrostatic voltmeter indicating up to 60,000 volts, it was found that whatever the intensity of the current traversing the tube if the voltage measured by the voltmeter was kept constant, the rays emitted by the tube are always sensibly of the same radio-chromometric degree For increased voltages of the tube the rays become more penetrating the variable intensities of current passing through the tube being without effect Finally for tubes of different patterns, unequally used and carrying different intensities of current provided that the voltages are kept equal the radio-chromometric degree of each is the same —The ultra-violet phosphorescent spectrum of fluorspar The variations of the phosphorescent spectrum of the same element in the same diluent G **Urbain** and C **Scal** The phosphorescence spectrum of an element cannot be considered as constant, but depends on the proportions in which it is present in the diluting medium —The chlorination of organic compounds in the presence of thallous chloride V **Thomas** The results obtained by the substitution of chloride of thallium for ferric chloride as a catalytic agent in chlorination are not essentially different in the two cases, complex mixtures being found —The alkaline reduction of *p*- and *m* nitrobenzophenone P **Carré** The complete reduction with zinc dust and caustic soda is not possible without affecting the ketonic group the mixture of azo and azoxybenzophenone resulting from this reduction furnished *p* hydrazobenzophenone on treatment with ammonium hydrosulphide —The use of polarised light for the detection under the microscope of starches composed of rice and maize in wheat flour G **Gastine** An improvement of a method proposed in an earlier paper —Fluorine in mineral waters P **Carles** The author has improved his method for the detection of traces of fluorine in mineral waters and gives approximate determinations of the amounts present in ninety-three waters of different origin —Artificial growths Stéphane **Leduc**. An account of the influence of the medium in which the artificial cells are produced —The influence of temperature and the hygrometric state of the surrounding atmosphere on the preservation of eggs M **de Loverdo** The most favourable conditions for the preservation of eggs are a temperature kept exactly at −1° C, and a hygrometric state as near as possible to 78 per cent saturated —The annelids collected by the French Antarctic Expedition Ch **Gravier** —The origin of the centrosome J **Kunstler** —The regulation of the nycthemeral cycle of temperature and its inversion in the aged Ed **Toulouse** and H **Piéron** —The Cretaceous strata of the eastern Atlas in Morocco W **Kilian** and Louis **Gentil** —The value of the magnetic elements at the Val Joyeux Observatory on January 1 Th **Moureaux**

NEW SOUTH WALES

Royal Society, November 7 1906 —Prof T P Anderson Stuart, president in the chair —Notes on some native tribes of Australia R H **Mathews**. The author reproduced some information he had collected during many years past among the aborigines of different portions of the continent respecting their sociology laws relating to food methods of avenging deaths and so on He also briefly touched upon their language and some curious beliefs held by the natives concerning metempsychosis or reincarnation of souls —Note on the Silurian and Devonian rocks occurring to the west of the Canoblas Mountains near Orange New South Wales C A **Süssmilch** The area referred to comprises a large portion of the parish of Barton and a small portion of the parish of Bowan county of Ashburnam, and is about fifteen miles south west from Orange

CAPE TOWN

South African Philosophical Society, November 28 1906 —Dr J C Beattie, president, in the chair —Notes on the morphology and biology of *Hydnora africana* Thunb Dr **Marloth** The genus Hydnora comprises several species (about seven), which are confined to the African continent They are all parasites which grow on

the roots of different shrubs and trees The species which forms the subject of this paper, viz *Hydnora africana*, uses the common milkbush of the karroo and karroid regions of the interior, viz *Euphorbia mauritanica*, as its host It is in the structure of the flower that the author has observed some organ which has hitherto escaped the attention of botanists Each of the three segments of the perianth bears a large snow-white body on its inner side, while the remainder of the inner surface of the flower is of a bright flesh colour These three white bodies are not mentioned in any existing description of Hydnora — Examination of the validity of an approximate solution of a certain velocity equation Prof A **Brown.** The question here considered is the part played by the initial value of $y(\lambda)$ in the solution of the equation

$$\frac{dy}{dt} = a_1 y + a_2 y^2 + a_3 y + - - -$$
